

CANCER

Thomas G. Brock, Ph.D.

Introduction to

Cancer

Radiation. Cancer. The emotional impact of these two words is immediate and dreadful for most people, and almost equally so. But radiation is essential to human health – so that as humans migrated northwards over the eons, evolution disabled the melanin shield in their skin to enable the life-giving UV light adequate penetration. But those same photons wreak havoc on our fragile strands of DNA, as illustrated in the cellular seascape on our cover. DNA-repair enzymes rush to the rescue, suggested by the crabs swarming to the nucleus. But when that repair fails, cancer often makes its appearance.

Unfortunately, prevention of cancer can never be as simple as fearful avoidance of sunlight and radiation. Cayman scientists have worked with the cancer researchers and doctors at the nearby University of Michigan, and our experience is that cancer causation is multifactorial and complicated. Cancer patients arrive every day of the year. They come from every ethnic group and economic class, from the young and the old. Cancer is so pervasive that almost every one of us knows a friend, a relative, perhaps a co-worker, who has cancer or perhaps had cancer. And, as cancer survivors know in a very personal and intimate way, the shadow of the disease lingers long after treatment has finished.

Cancer is the topic of this catalog and our purpose is to assist in research efforts to find cures for the varied forms of cancer. This catalog brings to the research community the best that Cayman offers toward the pursuit of fighting each of the many types of cancers. In addition, there are informative articles that are relevant to cancer, including the epigenetics of EZH2. Most importantly, this catalog serves as a bridge between you, the researcher, and Cayman. Cayman is an interactive company. We listen and respond positively to your requests for new compounds and products. Cayman also offers its expertise and facilities to you through our Contract Services, where we analyze your samples, run your samples in our assays, and perform custom chemical syntheses. Take a look at our website, caymanchem.com, or call us to find out how we can work together in the fight against cancer.

Cayman Chemical Company makes no warranty or guarantee of any kind, whether written or oral, expressed or implied, including without limitation, any warranty of fitness for a particular purpose, noninfringement, suitability, and merchantability, which extends beyond the description of the chemicals hereof. Cayman warrants only to the original customer that the material will meet our specifications at the time of delivery.

Cayman will carry out its delivery obligations with due care and skill. Thus, in no event will Cayman have any obligation or liability, whether in tort (including negligence) or in contract, for any direct, indirect, incidental, or consequential damages, even if Cayman is informed about their possible existence.

This limitation of liability does not apply in the case of intentional acts or negligence of Cayman, its directors or its employees.

Buyer's exclusive remedy and Cayman's sole liability hereunder shall be limited to a refund of the purchase price, or at Cayman's option, the replacement, at no cost to Buyer, of all material that does not meet our specifications.

Said refund or replacement is conditioned on Buyer giving written notice to Cayman within thirty (30) days after arrival of the material at its destination. Failure of Buyer to give said notice within thirty (30) days shall constitute a waiver by Buyer of all claims hereunder with respect to said material.

Neither party shall be liable to the other in any manner for the failure of or delay in the fulfillment of all or part of their obligations, resulting from causes or circumstances beyond their reasonable control including, but not limited to, floods, fires, hurricanes, tornadoes, earthquakes, other natural calamities and extraordinary weather, insurrections, wars, acts of terrorism, riots, embargoes, governmental refusals to issue approval for export, other governmental orders or restrictions, shortages of shipping vehicles, delays in transportation, inability to obtain supplies and materials, strikes, and lockouts.

Ordering Information
Orders are accepted by telephone, fax, mail, e-mail, or via the Cayman Chemical website. We will accept telephone orders Monday through Friday from 8 AM to 6 PM EST. All orders received by 1 PM EST will be shipped the same day if stock is available (Monday through Thursday only). Confirming purchase orders must be clearly marked as such to avoid possibility of duplication.

Domestic Shipments
In most instances we ship FedEx Standard Overnight Delivery (not available to all locations), with delivery by 3:30 PM of the next business day. Product availability may vary. Local delivery is available for the Ann Arbor area only. Other shipping options will be considered upon request, but can be granted only under conditions that will ensure the quality of the product. Freight is prepaid and added to the invoice. Please inquire at the time of order for an estimate of the freight charges. If you wish us to ship collect, please supply a valid account number when ordering. Please address all orders to:

Cayman Chemical Company
1180 E. Ellsworth Road
Ann Arbor, MI 48108 USA
Phone: (734) 971-3335

Toll-free Phone: (800) 364-9897
Fax: (734) 971-3640
E-mail: custserv@caymanchem.com
www.caymanchem.com

- Include the following information with your order:**
1. Catalog number, description, size, and quantity desired.
 2. Complete shipping address. (Delivery is not available to post office box numbers.)
 3. A complete billing address.
 4. A purchase order number or major credit card (Visa, MasterCard, or American Express), account number, and expiration date.
 5. Name of the end user.

- Terms**
1. U.S. funds only, drawn on a U.S. bank.
 2. Net 30 days.
 3. F.O.B. Ann Arbor, Michigan, U.S.A.
 4. Bank fees and wire transfer fees are not to be deducted from the invoice amount.

Prices
All prices listed are in U.S. dollars. The prices in this catalog are effective as of January 1, 2011. Prices are subject to change without notice.

Returns
Products cannot be returned without prior authorization from Cayman Chemical Company. Please contact our Customer Service Department for return shipping instructions. Custom orders and radioactive material cannot be accepted for return credit if due to a customer's error.

Technical Assistance
Technical assistance is available from 8 AM to 5:30 PM EST. If inquiring about a purchased product, please provide the catalog number, lot number, and date of purchase to our technical staff so they may answer your questions quickly. Technical assistance may be reached toll free at 888-526-5351, via e-mail at techserv@caymanchem.com, or on the web at www.caymanchem.com/techserv.

Use of Research Products
The products in this catalog are not for human or veterinary disease diagnosis or therapeutic drug use. They should be used only by technically qualified individuals or those under their direct supervision. Any individual working directly with these products should have free access to the applicable Material Safety Data Sheet (MSDS) and should read and understand it completely prior to use. Please contact our Customer Service Department or visit the specific product page on our website if you require additional copies of any MSDS.

Patent Disclaimer
The end-user assumes full responsibility for appropriate licensing and/or non-infringement for any proprietary claim or patent.

NOTE: For Laboratory Research Use Only. Not for human or veterinary diagnostic or therapeutic use.

Thomas G. Brock, Ph.D.

PGE₂, COX-2, and mPGES-1 in Cancer

This one molecule does it all. Prostaglandin E₂ (PGE₂) causes relaxation of smooth muscle in the kidney but contraction of smooth muscle in the peripheral vessels and airway. It promotes bone formation and inhibits sleep, causes fever and suppresses leukocyte function. PGE₂ is well known to induce fever and pain, but protects the gastrointestinal system by promoting duodenal bicarbonate secretion and inhibiting gastric acid production. It regulates circadian rhythms and inhibits lipolysis. PGE₂ is essential for ovarian follicle growth, promotes cervical relaxation and causes uterine contraction. Neonatal exposure to PGE₂ promotes masculinization in rat pups, whereas blocking PGE₂ leads to more female-like behaviors. The effects of PGE₂ are so diverse that, perhaps, it's not surprising that it's involved in a host of diseases.

In general terms, PGE₂ is best known as a pro-inflammatory mediator: it is over-produced at sites of inflammation, and it causes two cardinal characteristics of inflammation: pain and fever. It's likely that every person reading this article is familiar with over-the-counter pain treatments, although few may be aware that the primary target of non-steroidal anti-inflammatory drugs (NSAIDs) is PG production. More relevant to this catalog, PGE₂ may be involved in many types of cancer, including bladder, breast, cervical, colorectal, esophageal, head and neck, skin, lung, oral, and prostate cancers, as well as multiple myeloma. At first thought, it may seem reasonable that PGE₂ is linked with inflammatory aspects of these cancers and contributes to pain related to the disease. However, bear in mind that PGE₂ can do much more than cause pain. This article examines the sources of PGE₂ and its value as a biomarker in certain cancers.

The Sources of PGE₂

PGE₂ is a lipid mediator. As such, it can be distinguished from protein mediators (cytokines) on many levels. Lipid mediators are produced enzymatically from readily available precursors, so their levels can rise rapidly (in a matter of minutes), while cytokine synthesis is slower, involving transcription and translation. On the other hand, the continuous, low level production of PGE₂ is important in both normal and pathological circumstances. Lipid mediators can also be rapidly eliminated, through both enzymatic and non-enzymatic pathways. Related to this, the actions of lipid mediators like PGE₂ are local, affecting the source cell (described as 'autocrine' effects) or neighboring cells ('paracrine' actions). Remarkably, many lipid mediators, including PGE₂, act through specific receptors, much like cytokines.

The synthesis of PGs from arachidonic acid is initiated by the cyclooxygenases, COX-1 and COX-2 (Figure 1). Both enzymes are membrane-bound homodimers, found predominantly on the perinuclear membranes, including the endoplasmic reticulum. COX-1 is commonly described as ubiquitous and constitutively expressed. COX-2, on the other hand, is normally absent from most cell types, its expression is induced by inflammatory mediators like TNF- α and IL-1 β , and both its mRNA and protein have short half-lives. NSAIDs, including aspirin, ibuprofen, and indomethacin, non-selectively inhibit both COX-1 and COX-2, blocking the synthesis of all PGs. The overuse of NSAIDs can lead to damage in the gastrointestinal and renal systems through its inhibition of COX-1 (PGs have protective effects in these systems). This supports a generalization that COX-1 is 'good', producing products that are needed to maintain health and homeostasis, while COX-2 is 'bad'. Surprisingly, COX-2-selective NSAIDs, including celecoxib and rofecoxib, while effectively suppressing pain, have unwanted side effects, particularly in the cardiovascular system. Thus, even COX-2 has its good side.

Figure 1. COX-1 and COX-2 convert arachidonic acid to the intermediate PGH₂, which is then metabolized by specific distal enzymes to produce the different PGs and thromboxane. NSAIDs inhibit both COX forms, while the coxibs selectively inhibit COX-2.

In cancer, COX-2 is clearly bad. It appears to be over-expressed in many types of cancer, including colorectal, breast, prostate, lung, stomach, and esophageal cancers. Some of the most compelling data relates to individuals with familial adenomatous polyposis (FAP). In the classic form of this inherited disorder, benign growths (polyps) begin to appear in the colon during the teen years and increase in number throughout the next two decades. Some of these adenomas eventually transition into dysplasia, inevitably progressing to carcinoma in middle-aged adults. In both human FAP and murine models of the disease, COX-2 is constitutively over-expressed in the colon. Treatment with NSAIDs prevents tumor formation in mouse models of FAP.¹ More importantly, NSAIDs can produce a regression of intestinal adenomas and prevent colorectal cancer in humans.² These and numerous other studies have demonstrated that NSAIDs are chemopreventive in colorectal cancer. A recent international consensus statement reports that aspirin, because of its known cardiovascular benefit and available safety and efficacy data, is the 'most likely' NSAID for use in chemoprevention.³ In this report, other NSAIDs, either selective or non-selective for COX-2, were dismissed because they do not provide cardioprotection. In fact, COX-2 selective NSAIDs carry a documented risk of adverse cardiovascular effects, which argue against their persistent use as chemopreventive drugs.⁴ These problems may be attributed, at least in part, to cardioprotective effects of COX-2 products other than PGE₂, such as prostacyclin.⁵

The two COX enzymes produce only PG precursors (e.g., PGH₂); the synthesis of PGE₂ is completed by PGE synthases (PGES), of which three distinct human gene products are known. The first, microsomal PGES-1 (mPGES-1), is a membrane-associated protein, like COX-1 and COX-2.⁶ A 17.1 kDa protein that forms a homotrimer, it is highly expressed in human placenta, testis, small intestine, and colon, as well as in A549 cells (from a lung tumor) and HeLa cells (from cervical cancer). The expression of mPGES-1, like that of COX-2, is strongly and transiently induced by inflammatory mediators, giving rise to the paradigm that COX-2 and mPGES-1 are functionally coupled.⁶ A second enzyme, mPGES-2, is synthesized at the Golgi membrane, then cleaved to produce the mature, cytosolic enzyme. It is constitutively expressed in many normal tissues and is not induced by inflammatory mediators. Mice deficient in this enzyme

showed no change in PGE₂ production in several tests, raising the question of whether this enzyme is truly a PGE₂ synthase.⁷ Finally, cytosolic PGES (cPGES) is also known as p23 and associates with numerous proteins, including heat shock proteins Hsp70 and Hsp90. These complexes bind to genomic response elements in a hormone-dependent manner. Over-expression of cPGES in cells suggests that this enzyme converts PGH₂ derived from COX-1, but not COX-2, to PGE₂, functionally linking cPGES with COX-1.⁸

The enzyme mPGES-1 is currently considered a key target for therapeutic intervention in many diseases, including cancer.^{9,10} This enzyme is over-expressed in several types of cancer. Also, induced over-expression of mPGES-1 in experimental systems contributes to tumor growth, metastasis, angiogenesis, and resistance to apoptosis, whereas knockdown reverses these effects.¹¹⁻¹³ Thus, mPGES-1 appears, at this point, to be a better target for cancer treatment than COX-2. Certainly the inhibition of mPGES-1 is a more specific way to diminish PGE₂ synthesis.

PGE₂ Metabolites as Biomarkers

The COX enzymes initiate the synthesis of numerous products, including PGE₂, prostacyclin (PGI₂), thromboxane (TXA₂), PGD₂, and PGF_{2 α} . Each of these activates one or more selective GPCRs which are distributed on specific types of cells to generate distinctive physiological responses. For example, PGE₂ activates four 'E prostanoid' receptors, EP₁₋₄, and these activate different intracellular signaling pathways to alter cell function (described in detail in a related article on page 12). An overview of PGE₂ signaling is provided in Figure 2.

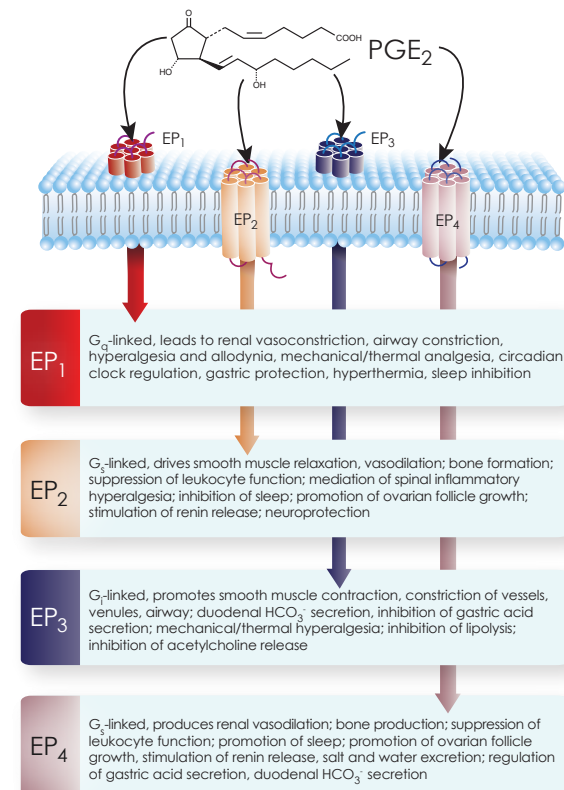

Figure 2. The four 'E prostanoid' (EP) receptors evoke distinct effects, in part due to differences in intracellular signaling.

Of all the COX products, it is primarily PGE₂ that has been associated with contributing to cancer. Interestingly, the induced expression of COX-2 does not simply lead to an increase in all COX products but tends to drive a selective overproduction of PGE₂.¹⁴ This is due, at least in part, to the concomitant increased expression of mPGES-1 with COX-2. In addition, PGE₂ feeds back to positively increase COX-2 expression, further augmenting its own synthesis. In the microenvironment of the tumor, this creates a vicious cycle

where tumor-related signaling increases COX-2 expression leading to PGE₂ production, which not only drives angiogenesis while suppressing apoptosis and innate immunity but also heightens COX-2 expression and perpetuates PGE₂ synthesis.

As mentioned above, PGE₂ acts in a very localized fashion and is rapidly metabolized. In serum and tissues, PGE₂ is rapidly metabolized to 15-keto PGE₂ by 15-hydroxy PG dehydrogenase (15-PGDH), an enzyme which can metabolize a variety of PGs in an NAD⁺-dependent fashion (Figure 3). 15-keto PGE₂ is further altered by additional enzymatic and non-enzymatic processes to produce 13,14-dihydro-15-keto-PGE₂ and tetranor PGEM. Reduced expression of 15-PGDH leads to prolonged availability and action of PGE₂ and has been linked to several cancers, including colorectal, bladder, pancreatic, and gastric adenocarcinomas.¹⁵⁻¹⁸ On the other hand, the expression of 15-PGDH is significantly increased in ovarian cancer.¹⁹

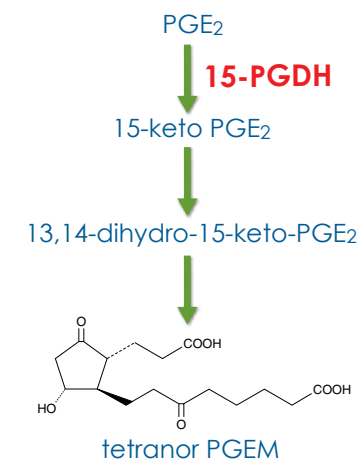

Figure 3. 15-PGDH is the gatekeeper of PGE₂ metabolism. Reduced 15-PGDH activity has been linked to several cancers.

There are two approaches to monitoring PGE₂ production in the context of cancer. First, PGE₂ itself can be measured in the media of cells studied in culture, since 15-PGDH, the critical enzyme for metabolizing PGE₂, is usually not produced by cells in culture. It may also be appropriate to measure PGE₂ in cancerous tissues, particularly when the level of 15-PGDH is expected to be suppressed. However, measuring the levels of PGE₂ metabolites in urine, such as 13,14-dihydro-15-keto-PGE₂, provides an indirect and non-invasive way to evaluate PGE₂ synthesis in the body as a whole. This approach has been used to demonstrate the increased synthesis of PGE₂ in individuals with colorectal and lung cancer.²⁰⁻²²

Cayman Chemical is a world leader in the analysis of PGs and their pathway enzymes. In the pages of this catalog, you will find many of the reagents, antibodies, and assays that we have available for research. For further information and additional products, please visit us at caymanchem.com.

7-AAD Cell Viability Assay Kit

10009856

7-Amino Actinomycin D

Stability: ≥1 year at 4°C

Summary: 7-AAD is a fluorescent dye which is excluded from live cells but penetrates dead or damaged cells to label DNA. Although 7-AAD fluorescence is less intense than that of propidium iodide, it exhibits a higher wavelength emission maximum (excitation at 488 nm, emission at 650 nm) and thus has minimal spectral overlap with PE or FITC. This makes 7-AAD preferable as a viability marker when FITC and/or PE are used simultaneously to label surface or intracellular antigens.

P-[[[(1R,2S)-2-aminocyclohexyl]amino]carbonyl]-phosphonic acid

Acetyl Lysine Monoclonal Antibody

(Clone 7F8)

10010567

Supplied as: Lyophilized IgG₁ **Stability:** ≥1 year at -20°C

Summary: Antigen: Acetylated KLH • Host: mouse • Cross Reactivity: (+) acetylated lysine residues; (-) non-acetylated lysine residues • Application(s): ELISA, ICC, and WB • Isotype: IgG₁ • This antibody is useful for monitoring levels of acetylation on various proteins (e.g., histone and p53). Histone subunit modifications such as lysine acetylation are regulated by the activity of HATs and HDACs. Epigenetic modifications directly influence cellular genetic programs including those contributing to cancer cell viability. This monoclonal antibody was generated using acetylated KLH as an immunogen.

1 ea

Acetyl Lysine Polyclonal Antibody-biotin

13725

Supplied as: Rabbit immunoglobulin **Stability:** ≥1 year at -20°C

Summary: Antigen: acetylated KLH • Host: rabbit • Cross Reactivity: (+) acetylated lysine residues; (-) non-acetylated proteins • Application(s): ELISA, IF, IP, and WB • Reversible lysine acetylation and deacetylation play critical roles in regulating gene transcription, cell cycle progression, apoptosis, DNA repair, and cytoskeletal organization. This biotin-tagged antibody is useful for monitoring levels of acetylation on various proteins.

400 µl

Acetyl Lysine Polyclonal Antibody

HRP Conjugate

13726

Supplied as: Rabbit immunoglobulin **Stability:** ≥1 year at -20°C

Summary: Antigen: acetylated KLH • Host: rabbit • Cross Reactivity: (+) • Application(s): ELISA, IF, IP, and WB • Reversible lysine acetylation and deacetylation play critical roles in regulating gene transcription, cell cycle progression, apoptosis, DNA repair, and cytoskeletal organization. This HRP-conjugated antibody is useful for monitoring levels of acetylation on various proteins.

400 µl

Acid Phosphatase Assay Kit

10008051

Stability: ≥6 months at 4°C

Summary: Cayman's Acid Phosphatase Assay provides a method for detecting AP activity in various matrices. The assay utilizes *para*-nitrophenyl phosphate (*p*NPP) as a chromogenic substrate for the enzyme. In the first step, AP dephosphorylates *p*NPP. In the second step, the phenolic OH-group is deprotonated under alkaline conditions resulting in *p*-nitrophenolate that yields an intense yellow color which can be measured at 405-414 nm.

7-[5α-([1S,1α(Z)-biphenyl]-4-ylmethoxy)-2β-(4-morpholinyl)-3-oxocyclopentyl]-4-heptenoic acid, calcium salt, hydrate

AIF Polyclonal Antibody

160773

*Apoptosis-Inducing Factor, Programmed Cell Death Protein 8***Supplied as:** Peptide affinity-purified IgG **Stability:** ≥2 years at -20°C

Summary: Antigen: human AIF amino acids 151-180 • Host: rabbit • Cross Reactivity: (+) human, rat, and murine AIF • Application(s): WB • AIF is a highly conserved mitochondrial protein with roles in redox-biochemistry and apoptosis.

500 µl

• Also Available: AIF Blocking Peptide (360773) 1 ea

Akt (human recombinant)

Western Ready Control

10010079

*Akt1, PKB, Protein Kinase B***Stability:** ≥2 years at -20°C

Summary: Source: human recombinant N-terminal His-tagged protein purified from Sf21 cells • Application(s): positive control for WB • M_r: 60.3 kDa (His-tagged), 57.3 (native)

1 ea

Aldehyde Reactive Probe (trifluoroacetate salt)

10009350

[627090-10-2] ARP, O-(Biotinylcarbazoylmethyl) Hydroxylamine

MF: C₁₂H₂₁N₅O₆S • C₂HF₃O₂ **FW:** 445.4 **Purity:** ≥98%A crystalline solid **Stability:** ≥2 years at -20°C

Summary: A biotinylated reagent used for the detection and quantification of apurinic/aprimidinic (AP) sites in damaged DNA; reacts with aldehyde groups formed when reactive oxygen species depurinate DNA, thereby covalently linking biotin to these AP sites

In Vitro Angiogenesis Assay Kit

10009964

Stability: ≥1 year at 4°C

Summary: Cayman's *In Vitro* Angiogenesis Assay uses a one-step model to study regulators of angiogenesis. Cell survival is improved compared to other assays by use of a modified extracellular matrix that has been validated in both short-term (2-3 days) and long-term (up to ten days) experiments. Cayman's *In Vitro* Angiogenesis Assay includes PMA and JNJ-10198409 as controls for stimulation and inhibition of angiogenesis, respectively, as well as the fluorescent dye Calcein AM for visualization of cell organization.

1 ea

Inhibition of network formation by JNJ-10198409. Panel A: CAPE cells suspended in culture medium containing 0.064 μM PMA or Panel B: 0.064 μM PMA + 0.3 μM JNJ-10198409 were seeded at a density of 6 × 10³ cells/well in a 96-well plate and grown in 37°C incubator for four days. On the fifth day, cells were stained with Calcein AM and the organization was examined under an inverted fluorescence microscope.

Annexin V FITC Assay Kit

600300

Stability: ≥1 year at 4°C

Summary: One of the hallmarks of the early stages of apoptosis is the redistribution of membrane phospholipids such as phosphatidylserine and phosphatidylethanolamine from the inner to outer leaflet of the membrane bilayer where they are exposed on the cell surface. Externalization of phosphatidylserine residues to the outer plasma membrane leaflet allows their detection *via* their high affinity for annexin V, a phospholipid binding protein. Cayman's Annexin-V Assay Kit employs a FITC-conjugated Annexin V as a probe for phosphatidylserine on the outer membrane of apoptotic cells. Apoptotic cells bound with fluorochrome-labeled annexin V can be visualized using fluorescence microscopy, flow cytometry, or a plate reader capable of fluorescence measurements. The reagents provided in the kit are sufficient to run 100 samples when using flow cytometry, or 500 samples when using a 96-well plate format.

100 tests

Staurosporine induces apoptosis in RAW 264.7 cells, as measured by an increase of annexin V FITC positive cells. RAW 264.7 cells treated with vehicle (control) or 8 μg/ml of staurosporine (treatment) for five hours processed for staining of dead cells and annexin V FITC. *Left Panel:* in control cells, there are a few propidium iodide positive dead cells (arrow heads) and few of these cells are from apoptosis (thick arrow, both propidium iodide and annexin V FITC positive). A thin arrow indicates a cell at an early apoptotic stage, which is annexin V FITC positive but propidium iodide negative. *Right Panel:* cells treated with 8 μg/ml of staurosporine show an increase in both propidium iodide positive cells (arrowheads), annexin V FITC positive cells (thin arrows), and cells which are both propidium iodide and annexin V FITC positive (thick arrows).

ANP32A Polyclonal Antibody

13783

Acidic Leucine-Rich Nuclear Phosphoprotein 32 Family Member A, Inhibitor-1 of Protein Phosphatase 2A, Leucine-Rich Acidic Nuclear Protein, Mapmodulin, PP32, Putative HLA-DR-Associated Protein 1

Supplied as: Protein G-purified IgG Stability: ≥1 year at -20°C

Summary: Antigen: synthetic peptides corresponding to human ANP32A amino acids 87-103 and 231-246 • Host: rabbit • Cross Reactivity: (+) chimpanzee, ovine, human, and rhesus monkey ANP32A • Application(s): WB • ANP32A has been implicated in proliferation, differentiation, apoptosis, suppression of transformation, inhibition of PP2A, regulation of mRNA trafficking and stability, and inhibition of acetyltransferases.

1 ea

Apaf-1 Polyclonal Antibody

160780

Apoptosis Protease-Activating Factor 1

Supplied as: Peptide affinity-purified IgG Stability: ≥1 year at 4°C

Summary: Antigen: human Apaf-1 amino acids 12-28; the sequence of the peptide is identical between human and mouse • Host: rabbit • Cross Reactivity: (+) human and murine Apaf-1 • Application(s): WB • Apaf-1 binds to cytochrome c (Apaf-2) and caspase-9 (Apaf-3), which leads to caspase-9 activation. Activated caspase-9 in turn cleaves and activates caspase-3, one of the key proteases responsible for the proteolytic cleavage of many key proteins in apoptosis.

500 μl

• Also Available: Apaf-1 Blocking Peptide (360780) 200 μg

Apoptotic Blebs Assay Kit

10010750

Stability: ≥6 months at 4°C

Summary: Cayman's Apoptotic Blebs Assay employs a recombinant protein derived from single chain variable fragments (scFv) of an antibody which preferentially binds to the autoantigen in membrane blebs of apoptotic cells. This recombinant protein is fused to protein A allowing visualization using fluorescein-conjugated rabbit IgG. This assay is specific for cells in the execution stage of apoptosis.

1 ea

Staurosporine induces apoptosis in Jurkat cells, as measured by an increase of apoptotic blebs. Panels A and B: apoptotic blebs in green (A) and dead cells in red (B) taken from the same field of control cells. Panels C and D: show apoptotic blebs in green (C) and dead cells from apoptosis in orange (D) taken from the same field of staurosporine-treated cells.

ARC Polyclonal Antibody

160737

Apoptosis Repressor with CARD

Supplied as: Affinity-purified IgG Stability: ≥1 year at 4°C

Summary: Antigen: human ARC amino acids 191-208 • Host: rabbit • Cross Reactivity: (+) human and murine ARC • Application(s): IP and WB • ARC interacts with caspase-2 and -8 and inhibits enzymatic activity of caspase-8. ARC suppresses apoptosis induced by cell death adapters FADD and TRADD and by cell death receptors Fas, TNFR-1, and DR3.

Thomas G. Brock, Ph.D.

EP₁ through EP₄: Targeting GPCRs in Cancer

The lipid mediator PGE₂, its metabolites, and its pathway enzymes COX-2 and microsomal PGE₂ synthase-1 (mPGES-1) are recognized contributors to many cancers (see related article on Page 4). Increased levels of PGE₂ and its metabolites are proven indicators of ongoing inflammation and/or cancer. COX-2 and mPGES-1 are considered viable targets for therapy. However, an alternative approach is emerging: modulating the receptors for PGE₂. PGE₂ activates four different 'E prostanoïd' (EP) receptors, EP₁₋₄. All are G protein-coupled receptors (GPCR). Each of these receptors may have distinct roles in certain cancers that may be agonized, inactivated, or silenced therapeutically to alter the course of disease.

Over 5,000 papers have been written linking PGE₂ and cancer. Compared to this body of work, only a few papers have looked at EP receptors in cancer. Even so, there's enough data to make some key points. First, it's interesting to note that two of the four EP receptors, being G_s-coupled, overlap in their intracellular signaling, while the third, which is G_i-coupled, actually initiates signaling pathways that oppose those evoked by the other two. The fourth, a G_q-coupled receptor, uses yet another pathway. Second, in spite of their differences, all four EP receptors appear to be involved in cancer, albeit in different processes. Naturally, this might suggest a balanced four-pronged attack by PGE₂ that leads to pathogenesis. Instead, a third point that emerges from the published research is that only one of the EP receptors is responsible for mediating the majority of PGE₂'s effects in many types of cancers.

EP₁, Calcium, and Cancer

EP₁ signals primarily through G_q, producing a transient rise in intracellular calcium (Figure 1). In this pathway, the interaction of PGE₂ with EP₁ converts GDP/G_q to GTP/G_q, evoking the release of GTP/G_q from the αβγ trimer and activation of phospholipase Cβ (PLCβ). PLCβ hydrolyzes phosphatidylinositol-4,5-phosphate (PIP₂) to generate diacylglycerol (DAG) and inositol-1,4,5-trisphosphate (IP₃). IP₃ binds to IP₃ receptors on the endoplasmic reticulum (ER), which act as calcium (Ca²⁺) channels, allowing the release of Ca²⁺ from intracellular stores within the ER to the cytoplasm. DAG and Ca²⁺ activate cell-specific Ca²⁺ channels at the cell surface, producing a further increase in cytoplasmic calcium. This transient increase in intracellular Ca²⁺ alters the activity of many proteins, including several isoforms of PKC. In this way, PGE₂ evokes Ca²⁺- and PKC-mediated effects in cells expressing EP₁. There are also reports that EP₁ can act through G_i, which is described below. The activation of EP₁ produces smooth muscle contraction, hyperalgesia, allodynia, and gastric cytoprotection. EP₁ has also been implicated in the resetting of the peripheral circadian clock, hyperthermia, sleep inhibition, and behavioral changes.

Figure 1. EP₁ signals primarily through G_q, which produces a transient rise in intracellular calcium.

Early studies with EP₁ knockout mice suggested an important role for this receptor in colon cancer: the development of aberrant crypt foci, putative preneoplastic lesions of the colon, were greatly reduced in EP₁ knockout mice treated with the colon carcinogen azoxymethane (AOM).¹ Similar results were obtained in wild type mice given an EP₁ antagonist, or in Min mice (a spontaneous colorectal cancer model) given the antagonist.¹ Longer studies demonstrated that mice lacking EP₁ displayed reduced colon cancer incidence and multiplicity as well as reduced tumor volume, compared to wild type mice, when given AOM.² On the other hand, an EP₁ antagonist significantly *decreased* invasive ductal adenocarcinomas in a mouse model of chemical-induced metastatic breast cancer.^{3,4} EP₁ was found in breast cancers but not in normal tissues. Antagonism of EP₁ induced apoptosis of cancer cells and prevented metastasis.^{3,4} PGE₂, acting through EP₁, has been shown to increase cell motility in oral cancer and chondrosarcoma cells, supporting the notion that EP₁ may increase metastasis in some cancers.^{5,6} Taken together, the data suggest that selective EP₁ blockers might be useful in blocking metastasis and tumor growth in certain cancers but not others.

EP₂ through EP₄ and cAMP

The remaining three EP receptors, EP_{2,4}, *vie* for control of cAMP production. EP₂ and EP₄ are coupled to G_s, which directs the synthesis of cAMP, while EP₃ is G_i-linked and acts to inhibit cAMP production (Figure 2). The principle enzyme, adenylate cyclase (AC), converts ATP to cAMP. Importantly, the inhibition of cAMP production by G_i is relevant for both reducing basal cAMP production, which can be appreciable in unstimulated cells, and blocking the increased cAMP generation in cells stimulated with ligands that activate G_s-coupled receptors, like EP₂ and EP₄.

The prototypical pathway activated by cAMP involves PKA. In resting cells, PKA exists as a tetramer of two regulatory subunits holding two catalytic subunits in an inactive state. The association of cAMP with the regulatory components causes dissociation of the tetramer, allowing the free and active catalytic subunits of the kinase to phosphorylate target proteins. A second pathway that is cAMP-dependent involves the membrane associated Exchange Proteins Activated by cAMP (Epac), which include Epac-1 and Epac-2. These are two of several guanine nucleotide exchange factors (GEFs) that modify the Ras GTPase homologs Rap1 and Rap2. Like the α subunits associated with GPCRs, the Rap proteins are activated when bound GDP is replaced with GTP by a GEF, like Epac. Hydrolysis of GTP to GDP *in situ* inactivates Rap. The cAMP-Epac-Rap pathway is involved in regulating a variety of different cell-specific processes, ranging from cell motility to gene expression.

As noted above, the βγ dimer, which is released from the heterotrimer following receptor activation, can also stimulate signaling pathways. There are multiple isoforms of γ, and some of those that associate with G_i can activate PLCβ. This triggers the usual signaling pathway that leads to increased intracellular Ca²⁺ and PKC activation, reminiscent of signaling through G_q. Thus, the activation of EP₃ can be monitored by measuring either cAMP or Ca²⁺.

EP₂ and EP₃ in Cancer

The EP₂ receptor is normally involved in vascular smooth muscle relaxation, bone formation, epithelial healing, neuroprotection, and suppression of leukocyte function. This receptor has been found to be relevant to many different types of cancers. It most commonly is linked to driving angiogenesis by promoting the expression of vascular endothelial growth

Figure 2. EP₂ and EP₄ are coupled to G_s, which directs the synthesis of cAMP, while EP₃ is G_i-linked and acts to inhibit cAMP production.

factor (VEGF).^{7,8} The promoter for VEGF contains a CREB response element,⁹ indicating a direct line from EP₂-mediated activation of PKA signaling to VEGF-driven angiogenesis. EP₂ signaling also up-regulates COX-2, positively amplifying PGE₂ production.¹⁰ This receptor has also been linked to the production of myeloid-derived suppressor cells (MDSC), which are a heterogeneous population of cells that expand during cancer and suppress both the anti-tumor functions of T and NK lymphocytes as well as dendritic cell maturation.¹¹ MDSC also promote tumor angiogenesis.¹² These results indicate that EP₂ antagonists would be useful for reducing angiogenesis, PGE₂ production, and the development of MDSC in cancer.

The EP₃ receptor has effects on smooth muscle, neurons, and epithelium, particularly in the small intestine, kidneys, pancreas, and vascular system. It normally modulates gastric acid secretion, sodium and water reabsorption in kidneys, neurotransmitter release, and smooth muscle contraction. At least seven splice variants which vary in their cytoplasmic tails have been described; the different functions of these isoforms are unknown. Of the four EP receptors, EP₃ is the least commonly linked to cancer, with most studies examining EP₃ knockout mice or EP₃-overexpressing cells. For example, mice deficient in EP₃ show less angiogenesis in a sponge implantation model and in Lewis lung carcinomas.¹³⁻¹⁵ The overexpression of EP₃ in human embryonic kidney cells, increases mRNA for VEGF and the VEGF receptor, VEGFR-1.¹⁶ While these results suggest that losing EP₃ should be good for cancer, EP₃ expression is markedly decreased in human colon cancer tissues and in colon tumors induced chemically in mice and rats.¹⁷ Similar results were found in some non-small cell lung carcinoma samples.¹⁸ In sum, EP₃ may play an indirect role in cancer, working outside the tumor to regulate pathways that contribute to angiogenesis.

EP₄ is Important in Cancer

While it's convenient to discuss each EP receptor in turn, this gives the misleading impression that all receptors are of equivalent importance. Consider this: a PubMed search for <EP₃ cancer> turns up some 85 papers, while EP₁ or EP₂ plus cancer roughly doubles the number and <EP₄ cancer> gives over 450 publications. More focused searches in PubMed for each of the EP receptors, combined with 'lung cancer', 'colorectal cancer', or 'carcinoma', again produces many more hits for EP₄ than EP₁, EP₂, or EP₃ in each of those types of cancers. The numbers become more impressive when you realize that many papers are comparing the importance of EP₄ with other receptors in certain processes. For example, deletion of EP₄, but not EP₂, suppresses the formation of aberrant crypt foci in chemical-induced colon cancer.¹⁹ The weight of evidence suggests that EP₄ is important in cancer.

Like EP₂, EP₄ increases cAMP, leading to phosphorylation of CREB and alteration of the expression of genes including VEGF and COX-2. Why might EP₄ be more involved in cancer than EP₂? In part, they differ in their cellular and tissue distribution, with EP₄ being more prevalent on gastric and renal epithelia. Perhaps more importantly, the expression of EP₄ can be increased in cancer tissues by diverse mechanisms.²⁰⁻²² This serves to amplify the impact of PGE₂ in cancer as well as focus the intracellular signaling down pathways activated by EP₄.

There is evidence for involvement of EP₄ in many different types of cancer. Further, EP₄ may affect essentially any cellular process, including angiogenesis, cell proliferation, apoptosis, cell motility, metastasis, and gene expression. While the majority of studies point to EP₄ as having undesirable effects in cancer, a recent study by Murn *et al.*, which portrays EP₄ as a candidate tumor suppressor, underscores the complexities of PGE₂ signaling.²³ This study shows that, in human B cells, EP₄ is a negative feedback regulator of proliferation in response to B cell receptor signals, suppressing growth in a PGE₂-dependent manner. In B cell lymphomas, EP₄ is down-regulated and growth suppression is diminished. This reminds us that EP₄ is normally expressed by diverse types of cells and evokes cell-specific actions. In fact, the effect of PGE₂-EP₄ signaling in one cell type may be the opposite of that in another cell type. These facts will need to be kept in mind as EP receptor actions are studied and therapeutic interventions are considered in the future.

CD34 Monoclonal Antibody (Clone ICO-115)

10004835

Supplied as: Peptide affinity-purified IgG₁ **Stability:** ≥1 year at 4°C**Summary:** Host: mouse, clone ICO-115 • Cross Reactivity: (+) human CD34 • Application(s): (+) FC and ICC (-) WB • CD34 is a type I transmembrane glycoprotein (M_r = 116 kDa). The antigen is expressed on stem cells and early hematopoietic progenitor cells, bone marrow stromal cells, endothelial cells, embryonic fibroblasts, and neurons. This anti-CD34 monoclonal antibody can be used for the differential staining of acute leukemia cells.

Cell Cycle Phase Determination Kit

10009349

Stability: ≥6 months at -20°C**Summary:** Cayman's Cell Cycle Phase Determination Kit provides an easy to use tool for studying the induction and inhibition of cell cycle progression in any cell suspension sample. The assay involves the fixation and permeabilization of the cells of interest, making possible the staining of DNA within intact cells by propidium iodide. This kit allows the investigator to determine the percentage of cells in a given sample that are within G₁/G₀, G₂, or S phase at the time of fixation, as well as to quantify cells in the sub-G₁ phase prior to apoptosis by FC.

CFSE Cell Division Assay Kit

10009853

Stability: ≥1 year at -20°C**Summary:** Carboxyfluorescein diacetate, succinimidyl ester (CFDA-SE) is a novel cell-tracing fluorescent dye used to examine the proliferative activity of cells by the labeling of a parent generation and the inheritance of the label by daughter generations. CFDA-SE diffuses into cells, where the acetate groups on the molecule are cleaved to yield a highly fluorescent derivative (CFSE) that is retained in the cell and can be detected by FC. Cell division results in sequential halving of fluorescence, and up to eight divisions can be monitored before the fluorescence is decreased to the background fluorescence of unstained cells.

100 tests

**BDCM (a human DC-like cell line which can be obtained from ATCC) stimulates T cell proliferation when the cells are co-cultured together for six days.** Human peripheral blood lymphocytes isolated from freshly collected blood were labeled with CFSE on Day 0. CFSE-labeled lymphocytes were then co-cultured with BDCM cells at a ratio of 25:1 in 2 ml of RPMI culture medium in a 6-well plate for three to six days. **Panel A:** CFSE fluorescence intensity is strong at the time of staining (Day 0). **Panel B and C:** CFSE staining intensity drops rapidly in the first couple of days due to catabolism. As cell division occurs, the staining intensity stabilized (Day 3 and Day 6). **Panel C:** Eight peaks representing successive cell cycles of lymphocytes were detected after six days of BDCM stimulation (the first peak shown here actually contains two peaks representing undivided cells, peak 0, and first division cells, peak 1).

COX Fluorescent Activity Assay Kit 700200

Stability: ≥1 year at -80°C**Summary:** Cayman's COX Fluorescent Activity Assay provides a convenient fluorescence-based method for detecting COX-1 or COX-2 activity in both crude (cell lysates/tissue homogenates) and purified enzyme preparations. The assay utilizes the peroxidase component of COXs. In this assay, the reaction between PGG₂ and ADHP produces the highly fluorescent compound resorufin that can be analyzed using an excitation wavelength between 530-540 nm and an emission wavelength between 585-595 nm. The kit includes isozyme-specific inhibitors for distinguishing COX-2 activity from COX-1 activity.

2 x 96 wells

COX activity was detected in LPS/IFN_γ-stimulated RAW (murine macrophage) cell lysates. COX fluorescence was compared to cells that were not treated with LPS/IFN_γ (Control = Ctr). Control cells contained COX-1 and stimulated cells contained both the constitutive COX-1 and the induced COX-2 (Ctr = Control; Stim = Stimulated with LPS/IFN_γ).

COX Fluorescent Inhibitor Screening Assay Kit 700100

Stability: ≥1 year at -80°C**Summary:** Cayman's COX Fluorescent Inhibitor Screening Assay provides a fluorescence-based method for screening ovine COX-1 and human recombinant COX-2 for isozyme-specific inhibitors. In this assay, the peroxidase-catalyzed reaction between PGG₂ and ADHP produces the highly fluorescent compound resorufin. The kit includes both ovine COX-1 and human recombinant COX-2 in order to screen isozyme-specific inhibitors.

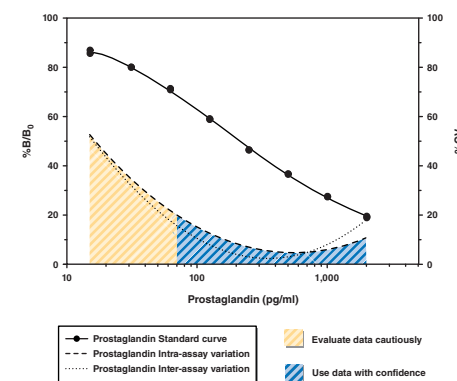

96 wells

• Also Available: **Colorimetric COX (ovine) Inhibitor Screening Assay Kit (760111)** 96 wells

COX Inhibitor Screening Assay Kit 560131

Stability: ≥1 year at -80°C**Summary:** Cayman's COX Inhibitor Screening Assay directly measures PGF_{2α} produced by SnCl₂ reduction of COX-derived PGH₂. The prostanoid product is quantified *via* EIA using a broadly specific antibody that binds to all the major PG compounds. The kit includes both ovine COX-1 and human recombinant COX-2 in order to screen isozyme-specific inhibitors.

96 wells

• Also Available: **COX (ovine) Inhibitor Screening Assay Kit (560101)** 96 wells

COX-2 (human recombinant) 60122

PGH Synthase 2

Thomas G. Brock, Ph.D.

Inflammation in Cancer

Everyone has a feel for the term 'inflammation'. Who hasn't taken anti-inflammatory drugs for joint or muscle pain? Inflammatory words arouse anger. "Inflamed" connotes 'set ablaze'. But what is inflammation, physiologically? Merriam-Webster puts it this way: "a local response to cellular injury that is marked by capillary dilatation, leukocytic infiltration, redness, heat, and pain and that serves as a mechanism initiating the elimination of noxious agents and of damaged tissue". Such a definition tries to paint, in broad strokes, a term that is applied to a wide variety of processes that may be initiated by diverse triggers, may involve some or all of the listed markers, and can lead to a range of outcomes. Inflammation resulting from a bacterial infection in a skin abrasion differs distinctly from the inflammation of an arthritic joint, which in turn is vastly different from the painful, swollen response to a bee sting. In short, the devil is in the details. The same applies to the potential relevance of inflammation to cancer. Distinct types of inflammatory processes may be involved in causing, or contributing to, different types of cancer. Totally different aspects of inflammation may act during cancer, promoting such processes as metastasis or angiogenesis.

Infections, Inflammation, and Cancer

Sometimes, it may seem that infection and inflammation go hand-in-hand. However, some of the most effective pathogens are those that avoid evoking a host response. Similarly, there are many inflammatory triggers that are not infectious agents. Certainly, there are many pathogens that cause cancer and inflammatory signaling is commonly, but not always, a necessary intermediary. This topic is introduced in another article on page 48. The important point of overlap of all of these processes is host innate immunity. Bacterial infections, in particular, excite signaling pathways in tissue-resident immune cells, including dendritic cells (DC) and macrophages (M ϕ), which cause the infiltration of leukocytes from the circulation into the infected tissue. Leukocytes in neoplastic tissues were first noted in 1863 by Dr. Rudolf Virchow, who has been described as the 'Father of Modern Pathology'. He proposed that these overly abundant white cells reflected the origin of cancer at sites of chronic inflammation. While it may be argued that he was observing a correlation rather than causation, his observation certainly presaged many aspects of contemporary cancer research. Moreover, Virchow's notorious stance against a role for bacteria as a causative agent in disease, when combined with the observation of leukocytic infiltrates in tumors, nicely predicts that inflammation, in the absence of infection, must be important in the maintenance of tumors or progression of cancer. The questions become: what are these leukocytes and what are they doing?

Lymphocytes

While CD8⁺ cytotoxic T lymphocytes (CTL) and natural killer (NK) cells play recognized roles in restraining tumor development,¹ CD4⁺ helper cells have more diverse functions. CD4⁺ lymphocytes differentiate into different functional subsets, depending on the cytokine signals present during activation.² These include the T_h1, T_h2, T_h17, and T_{reg} subsets (Figure 1). Each subset has distinct roles in cancer.

The T_h1 type of lymphocyte is induced when CD4⁺ cells are activated in the presence of interleukin (IL)-12, IL-18, and IL-27. These cells secrete tumor necrosis factor (TNF)- α , interferon (IFN)- γ , IL-2, MCP-1, and IL-12. Through these chemical messengers, T_h1 cells regulate immune surveillance programs by increasing antigen processing and presentation by DC and M ϕ , particularly against bacteria, fungi, and viruses. In this way, T_h1 cells control the duration and magnitude of CD8⁺ CTL activation. Moreover, T_h1 cells contribute directly to the killing of tumor cells by

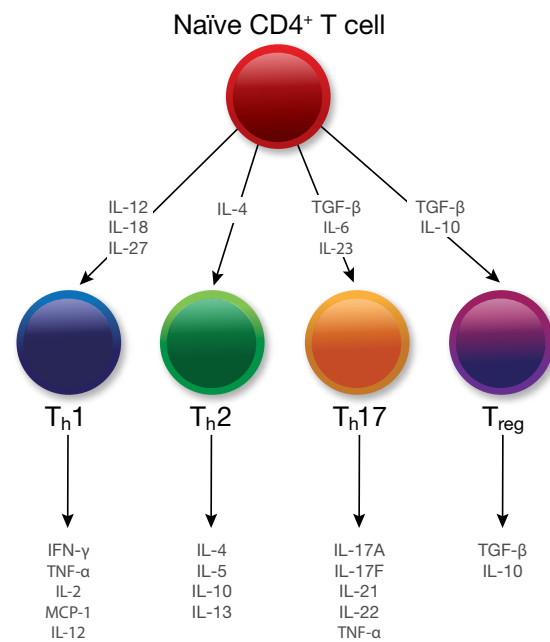

Figure 1. Naïve CD4⁺ T cells differentiate in response to specific mediators. The resulting T cells differ in the types of mediators they produce and their roles in immunity.

secreting high levels of TNF- α and IFN- γ . Thus, T_h1 cells are decidedly anti-cancer lymphocytes.

T_h2-type CD4⁺ cells are induced by IL-4. They secrete high levels of IL-4, IL-5, IL-10, and IL-13, which induce T cell anergy and inhibit T cell-mediated cytotoxicity. The T_h2 response is often associated with humoral responses during which high levels of pathogen-specific antibody are produced to neutralize foreign invaders, including helminths and nematodes. While T_h2 cells can inhibit apoptosis and stimulate cell proliferation in some types of cells, they are considered more relevant to allergic and antibody-mediated responses, than to cancer.

In the presence of IL-6/IL-23 and transforming growth factor (TGF)- β , CD4⁺ cells differentiate into T_h17 lymphocytes. These secrete IL-17A, IL-17F, IL-21, TNF- α , and IL-22, mounting a defense against extracellular pathogens and regulating autoimmune disease. Naturally-occurring T_h17 cells have been found in tumors.³ As IL-17 can promote angiogenesis and tumor growth, these cells may actually facilitate tumor survival. Interestingly, T_h17 cells can acquire T_h1-like characteristics by a variety of stimuli, including IFN- γ , IL-12, and IL-23.⁴ This suggests that tumor-resident T_h17 lymphocytes may be converted into tumor-killing cells as a therapeutic approach to treating cancer.

TGF- β alone or in combination with IL-10 can generate T_{reg}, or suppressor T, cells. They secrete TGF- β and IL-10 and suppress activation of the immune system. In this way, they counter the effects of activating signals, maintaining immune system homeostasis. As they suppress the anti-tumor activities of CD8⁺ and NK lymphocytes, increased numbers of T_{reg} cells typically correlate with poorer prognosis for survival.

While these are some of the types of T cells that develop under normal circumstances, distinctive types of lymphocytes are usually found within established tumors. These tumor-infiltrating lymphocytes (TIL) typically contain a mix of CD4⁺, CD8⁺, and NK cells, as well as CD4/CD8⁺ cells.⁵⁻⁷

CD8⁺ TIL may secrete IL-17, like T_h17 cells, and may actually promote tumor growth.⁶ The majority of TIL lack cytotoxic activity or the ability to make the immunostimulatory cytokine IFN- γ .⁷ CD4⁺/CD8⁺ lymphocytes produce the anti-inflammatory cytokine IL-10, suppressing immune function within the tumor.⁵ While TIL poorly fight cancer from within the tumor, they may be isolated from malignant tissue and greatly expanded *ex vivo*, then returned to the patient, where, in some cases, they effectively target and kill tumors.

Macrophages (M ϕ)

In addition to phagocytosing multitudes of bacteria, dead cells, and debris, M ϕ professionally present antigen to lymphocytes and secrete diverse mediators to modulate immune function. Resident tissue M ϕ are known by many names, including Kupffer cells (liver), microglia (brain), osteoclasts (bone), and histiocytes (connective tissue). Like T-cells, M ϕ change phenotype and function in response to different cues (Figure 2).^{8,9} The classically activated M ϕ , denoted M1 to parallel the T_h1 nomenclature for lymphocytes, are induced by inflammatory mediators, like IFN- γ and TNF- α , produced by T_h1 cells. These cells have heightened microbicidal activity. Moreover, they secrete cytokines (TNF- α , IL-12, and IL-23) that modulate T_h1 and T_h17 cell function.

Figure 2. Monocytes from peripheral blood differentiate in response to mediators in tissues, giving rise to pro-inflammatory M1 macrophages or regulatory M2 macrophages.

Alternatively-activated, M2 M ϕ are induced by either the T_h2 cytokines IL-4 and IL-13 (M2a), immune complexes (M2b), or the immunosuppressive mediators IL-10, PGE₂, and TGF- β (M2c). M2a cells are important in mediating tissue repair, while M2c cells have regulatory or anti-inflammatory actions.

Tumor-associated M ϕ (TAMs) come from blood monocytes that are recruited at the tumor site by tumor-derived CCL2 (also known as monocyte chemoattractant protein, MCP-1).^{10,11} At the tumor, these monocytes become M2-like, secreting modulators that down-regulate adaptive immunity while promoting tumor growth, angiogenesis, and metastasis. These molecules include IL-10, IL-1R decoy, CCL17 (TARC), CCL22, and CCL18 (PARC).

TGF- β is a pleiotropic cytokine that can be produced by tumors and have multiple pro-oncogenic effects, including promoting angiogenesis and suppressing the immune response. It contributes to the differentiation of CD4⁺ cells to T_h17 and T_{reg} subsets and drives M ϕ to the immunosuppressive M2c type. In addition, TGF- β inhibits the activation of naïve CD8⁺ CTL. For these reasons, TGF- β blockers (soluble receptors or antibodies) and TGF- β receptor inhibitors have anti-tumor effects. Interestingly, TGF- β blockade also promotes an influx of tumor-associated neutrophils (TAN) with an anti-tumor phenotype.¹² Thus, therapeutic intervention at TGF- β

action should facilitate tumor removal through several innate immune mechanisms.

An Epigenetic Link?

Why do tumors produce TGF- β ? Epigenetics can play a pivotal role in oncogenesis. For example, overexpression of the histone methyltransferase EZH2 is associated with prostate, breast, and other cancers. EZH2 is an example of a protein which persistently alters the nucleosome, changing the ability of gene regulators to control the expression of a cluster of genes. It is the active component of polycomb repressive complex 2 (PRC2), which, at least in part, maintains a stem cell-like phenotype, as is found in the proliferative, poorly differentiated tumor cell. There is clear evidence that stem cells, and in particular the so-called 'cancer stem cell', produce TGF- β .¹³ There is also some evidence that EZH2, as well as other epigenetic regulators, can increase TGF- β expression.^{14,15} It remains to be determined if therapies that alter epigenetic regulators, like EZH2, effectively reduce TGF- β signaling.

Myeloid-Derived Suppressor Cells

Tumor-derived mediators, including TGF- β and PGE₂, commonly enter the blood stream and marrow, where they alter the development of myeloid stem cells and progenitors, pushing them to become active suppressor cells (Figure 3). As each type of tumor secretes a distinctive mix of messengers, differentiation of myeloid cells is highly variable and the resulting myeloid-derived suppressor cells (MDSC) are heterogeneous. However, as a group, MDSC potently suppress different aspects of immune response, including T cell function. Monocytic MDSC can associate with tumors, become TAMs, and promote angiogenesis and metastasis. Importantly, MDSC occur in many conditions in addition to cancer, such as sepsis, trauma, and infection. Because MDSC actively suppress immunity, they represent a major barrier to immunotherapies that require functional innate and adaptive immune responses.^{16,17}

Figure 3. Tumor-derived mediators and complement component C5a alter the differentiation of myeloid stem cells to produce MDSC. MDSC secrete mediators that suppress the action of mature leukocytes and enhance tumor survival.

480 strip/solid wells

Cytokeratin Monoclonal Antibody (Clone C-11) 10004600

pan-Cytokeratin

Supplied as: Affinity-purified IgG₁ **Stability:** ≥1 year at 4°C**Summary:** Host: mouse, clone C-11 • Cross Reactivity: (+) human cytokeratins 4, 5, 6, 8, 10, 13, and 18 • Application(s): FCC, ICC, IHC (paraffin-embedded sections), and WB • Cytokeratins make up a large family of proteins classified as intermediate filament polypeptides. They are subdivided into type I (acidic) and type II (basic/neutral) proteins. Under normal conditions, these proteins are found in epithelial cells as type I/type II pairs. These pairs provide cellular support as well as contribute to more dynamic processes. They undergo extensive post translational modifications, such as phosphorylation, and are important for cancer diagnostics.

Cytokeratin Monoclonal FITC Antibody (Clone C-11) 10349

pan-Cytokeratin

Supplied as: Fluorescein-labeled IgG₁ **Stability:** ≥1 year at 4°C**Summary:** Host: mouse, clone C-11 • Cross Reactivity: (+) human cytokeratins 4, 5, 6, 8, 10, 13, and 18 • Application(s): FC and IF • Cytokeratins are intermediate filament polypeptides that provide cellular support to epithelial cells as well as contribute to more dynamic processes. Cytokeratins are differentially expressed in normal and cancer cells.

1 ea

Cytokeratin Monoclonal PE Antibody (Clone C-11) 10478

pan-Cytokeratin

Supplied as: Lyophilized purified IgG₁ **Stability:** ≥1 year at 4°C**Summary:** Host: mouse, clone C-11 • Cross Reactivity: (+) human cytokeratins 4, 5, 6, 8, 10, 13, and 18 • Application(s): FC and IF • Cytokeratins are intermediate filament polypeptides that provide cellular support to epithelial cells as well as contribute to more dynamic processes. Cytokeratins are differentially expressed in normal and cancer cells.

Demethylase (Jumonji-type) Activity Assay Kit 700390

Stability: ≥6 months at -80°C**Summary:** Lysine demethylases containing Jumonji C (JmjC) domains produce formaldehyde following 2-oxoglutarate-dependent demethylation. Cayman's Demethylase (Jumonji-type) Activity Assay provides a convenient fluorescence-based method for assaying JmjC-mediated demethylase activity from cell lysates or purified enzyme preparations. The assay is based on the production of formaldehyde during the demethylation of a peptide substrate. Cyclization of formaldehyde and acetoacetanilide in the presence of ammonia gives a fluorescent product for quantitation.

96 wells

Demethylase (LSD-type) Activity Assay Kit 700400

Stability: ≥6 months at -80°C**Summary:** Cayman's Demethylase (LSD-type) Activity Assay provides a fluorescence-based method for assaying LSD-type demethylase activity. In this assay, formaldehyde is measured directly, eliminating the need for a coupled-enzyme reaction system. Formaldehyde, produced during demethylation of lysine 4 on a histone H3 peptide, reacts with the detection reagents provided in the kit to give a brightly fluorescent product. The assay is easy to use and can be completed in under two hours.

DNA Methylation EIA Kit 589324

5-methyl-2-deoxy Cytidine

Stability: ≥1 year at -20°C**Sensitivity:** 50% B/B₀: ~12 ng/ml • 80% B/B₀: ~3 ng/ml**Summary:** DNA methylation is an important epigenetic process regulating gene expression. Methylation occurs on carbon 5 of 2-deoxy cytidine yielding the modified base 5-methyl-2-deoxy cytidine. Methylation results in long-term silencing of genes, while unmethylated regions of DNA can be actively transcribed. Cayman's DNA Methylation EIA is a competitive assay that can be used for quantification of 5-methyl-2-deoxy cytidine in urine, culture supernatants, plasma, and other sample matrices.

ERK/MAPK (Phospho-Thr²⁰²/Tyr²⁰⁴) Cell-Based Phosphorylation/Translocation Assay Kit

10010549

Stability: ≥1 year at -20°C**Summary:** Cayman's ERK/MAPK (Phospho-Thr²⁰²/Tyr²⁰⁴) Cell-Based Phosphorylation/Translocation Assay Kit provides the tools necessary to study ERK/MAPK phosphorylation and translocation within whole cells. The kit contains a phospho-specific ERK/MAPK (Phospho-Thr²⁰² and Tyr²⁰⁴) primary antibody together with a Dylight (product of Pierce Biotechnology, Inc.) conjugated secondary antibody in a ready-to-use format. Tamoxifen, which has been shown by scientists at Cayman Chemical to cause the translocation of phosphorylated ERK/MAPK (Phospho-Thr²⁰²/Tyr²⁰⁴) between the cytoplasm and nuclear compartments, is included as a positive control.

1 ea

**Tamoxifen induces the translocation of ERK/MAPK (Phospho-Thr²⁰²/Tyr²⁰⁴) from the cytoplasm to the nucleus in MCF-7 cells.** Cells were plated at 1 x 10⁵ cells/well in a 96-well plate and grown in DMEM containing 10% FBS overnight. **Panel A:** Cells were then treated with vehicle **Panel B:** 20 µM tamoxifen for 20 minutes. The cells were processed for immunostaining with the ERK/MAPK (Phospho-Thr²⁰²/Tyr²⁰⁴) antibody following the immunofluorescent staining protocol described above. Translocation of the phosphorylated ERK from the cytoplasm to the nucleus by tamoxifen treatment is evident.

Epigenetics Enzyme Inhibitors		
Item No.	Item Name	
13145	AGK2	A cell-permeable, selective inhibitor of SIRT2 (IC ₅₀ = 3.5 µM) that minimally affects either SIRT1 or SIRT3 at 10-fold higher levels
13144	Anacardic Acid	Inhibits the HAT activity of the transcription co-activators p300 and p300/CREB-binding protein-associated factor (pCAF) with IC ₅₀ values of 8.5 and 5 µM, respectively
13373	2',3',5'-triacetyl-5-Azacytidine	A prodrug form of a DNA methyltransferase inhibitor
13124	BIX01294 (hydrochloride hydrate)	A selective inhibitor of G9a HMTase (IC ₅₀ = 1.7 µM)
89740	CAY10398	Inhibits HDAC1 with an IC ₅₀ value of 10 µM
10005019	CAY10433	HDAC inhibitor with an IC ₅₀ value of 30 µM
13146	CAY10603	A potent, selective inhibitor of HDAC6 (IC ₅₀ = 0.002 nM)
13172	CBHA	A potent HDAC1 and HDAC3 inhibitor; ID ₅₀ values equal 0.01 and 0.07 µM <i>in vitro</i> , respectively
13156	Chaetocin	A fungal mycotoxin that inhibits the HMT SU(VAR)3-9 (IC ₅₀ = 0.8 µM)
13686	Chidamide	An HDAC inhibitor that increases histone H3 acetylation levels in LoVo and and HT29 colon cancer cells at concentrations as low as 4 µM
10569	Ellagic Acid	Blocks methylation of arginine 17 of histone 3 (H3R17) by CARM1
10009798	EX-527	A cell-permeable, selective inhibitor of SIRT1 (IC ₅₀ = 98 nM)
10576	HC Toxin	A cell-permeable, reversible inhibitor of HDACs (IC ₅₀ = 30 nM)
13277	(S)-HDAC-42	A potent inhibitor of HDACs (IC ₅₀ = 16 nM, <i>in vitro</i>)
13295	HNHA	A cell-permeable inhibitor of HDAC activity (IC ₅₀ = 8 µM)
13174	M 344	Inhibits maize HDAC (IC ₅₀ = 100 nM) as well as human HDAC1 (IC ₅₀ = 46 nM)
13284	MS-275	Preferentially inhibits HDAC1 (IC ₅₀ = 300 nM) over HDAC3 (IC ₅₀ = 8 µM)
13176	Oxamflatin	A potent inhibitor of HDACs (IC ₅₀ = 15.7 nM)
13212	Pimelic Diphenylamide 106	Inhibits the class I HDACs (IC ₅₀ = 150, 760, 370, and 5,000 nM for HDAC1, 2, 3, and 8, respectively), but not the class II HDACs (IC ₅₀ > 180 µM for HDAC4, 5, and 7)
10009929	SAHA	Inhibits class I and II HDACs at around 50 nM
13178	Salemide	An inhibitor of SIRT1 and SIRT2, causing tumor-specific apoptotic cell death
10572	Scriptaid	An HDAC inhibitor that has an optimal concentration of 6-8 µM in a cell-based assay; is less toxic than trichostatin A
13121	Sodium Butyrate	HDAC inhibitor
13168	Splitomicin	An inhibitor of Sir2p HDAC activity, displaying higher activity <i>in vivo</i> (minimal IC = 0.49 µM) than <i>in vitro</i> (IC ₅₀ = 60 µM)
10574	Suberohydroxamic Acid	Inhibits HDAC1 (IC ₅₀ = 0.25 µM) and HDAC3 (IC ₅₀ = 0.30 µM)
13085	Tenovin-1	Inhibits the deacetylase activity of purified human SIRT1 and SIRT2

Epigenetics Enzyme Inhibitors Continued

Item No.	Item Name	
13086	Tenovin-6	Inhibits the protein deacetylase activities of purified human SIRT1, 2, and 3 <i>in vitro</i> with IC ₅₀ values of 21, 10, and 67 µM, respectively
89730	Trichostatin A	A potent, reversible inhibitor of HDAC1 with an IC ₅₀ value of 70 nM
13631	UNC0224	A potent and selective G9a HMTase inhibitor, exhibiting an IC ₅₀ value of 15 nM
10582	UNC0321	A highly potent, selective G9a inhibitor K _i = 63 pM
13033	Valproic Acid (sodium salt)	Inhibits class I HDACs with an IC ₅₀ value of ~2 mM

ERK/MAPK (Phospho-Thr²⁰²/Tyr²⁰⁴) Polyclonal Antibody 10009179**Supplied as:** Affinity-purified IgG **Stability:** ≥1 year at -20°C**Summary:** Antigen: phosphopeptide corresponding to amino acid residues surrounding phospho-Thr²⁰² and phospho-Tyr²⁰⁴ of rat ERK/MAPK • Host: rabbit • Cross Reactivity: (+) human and rat ERK/MAPK • Application(s): WB • ERK/MAPK is an integral component of cellular signaling during mitogenesis and differentiation of mitotic cells and also is thought to play a key role in learning and memory. The activity of this kinase is regulated by dual phosphorylation at Thr²⁰² and Tyr²⁰⁴.

Epigenetics in Cancer as Modeled by EZH2

Years ago, the causes of cancer boiled down to a simple dichotomy. Tumors could either be initiated by external factors, including carcinogens or viruses, or they arose from inherited internal (genetic) defects. The line between these two options became blurred with the understanding that carcinogens cause genetic changes to produce cancer. Thus, the study of cancer narrowed to a quest for the key mutations associated with each type of cancer, what aspect of the disease the gene defect produced, and what (if anything) could be done given the permanent change in DNA sequence.

Enter epigenetics. In broad terms, 'epigenetics' refers to heritable changes in gene expression that do not involve changes in DNA sequence or copy number. The more intriguing cases relate to how factors impacting parents have long-lasting effects on the health of offspring, even years after birth. A popular example centers on how the diet of the mother reprograms the genes of the fetus, without mutation, leading to persistent effects in health and development of the child.¹ In more molecular terms, epigenetic changes may involve adding or removing various "marks" on chromatin. The marks are chemical modifications, like methyl groups, and they can be added to or removed from DNA and the histones at the core of the chromatin. In theory, the pattern of marks in the genome is persistent, commonly passed down through both mitosis and meiosis. Critical events at pivotal times may alter a few key marks, producing a new epigenomic pattern of marks that are continued in ensuing cells. This system of generating lasting changes in gene expression is active in differentiation and development. Unfortunately, when it goes awry, it contributes to disease, with cancer being a prominent example.

Getting Started

In the 1990's, the Human Genome Project was sequencing human DNA and scientists were sifting through potential oncogenes. Little was written about epigenetics through the decade. Then, around the start of the new millennium, the field of epigenetics tipped, as reports of new proto-oncogenes started to appear from labs around the world. In 1999 Carlos Caldas' group from Cambridge in the UK reported the discovery of the mixed lineage leukemia homolog MLL2 associated with pancreatic and glioblastoma cell lines.² This gene, which is amplified in cancers, was later found to encode a lysine (K) methyltransferase (MT) (recently renamed KMT2B), which places methyl groups on lysine 4 of histone 3 in the nucleosome. From Tokyo in 2000, Inazawa and colleagues cloned GASC1 (gene amplified in squamous cell carcinoma 1) from esophageal cancer cells.³ They identified, within the deduced amino acid sequence, potential oncogenic motifs, patterns present on other recently-described nuclear proteins involved in chromatin-mediated transcriptional regulation. We now know that GASC1 is a lysine-specific demethylase and has the function-related name of KDM4C. With the discovery of these and literally dozens of other enzymes that are active in modulating transcription by marking nucleosomes came a burst of interest in epigenetics (Figure 1).

Around the same time, Carlos Cardoso and colleagues, from Paris, and Raaphorst's team from Amsterdam characterized EZH2 (enhancer of zeste homolog 2) and linked it to cancer, although the precise function of this protein was, as yet, unknown.^{4,5} EZH2 was known to be the human equivalent of the *Drosophila* protein Enhancer of Zeste (E(z)), a member of the polycomb group (PcG) proteins involved in regulating embryonic development and cell cycle control in flies. The possibility that a PcG protein was also involved in oncogenesis was a novel idea and led to an increased number of studies on EZH2 function in mammals (Figure 1). We now know that EZH2 is a histone methyltransferase, with the function-related name of KMT6.

Figure 1. Annual publication rate A.) of epigenetics papers, and B.) of EZH2 papers (green: cancer-related; blue: total) in PubMed

Polycomb and Trithorax Groups

Fly geneticists have long studied homeosis, where, during fly development, one structure is replaced by another that normally develops elsewhere. For example, a leg might form where an antenna should normally be found. In the 1970's, fly development was conceptually divided into an early 'determination' process and its observable consequences of differentiation and morphogenesis.⁶ The hot question was: what occurs during 'determination'? What is the mechanism that sets in place, at an earlier time, all that is determined to unfold over an extended period of development? Part of the answer relates to genes that act on genes. The genes Polycomb (Pc) and Extra sex comb (Scx, now Antp) were first identified based on their effects on the *Drosophila* sex comb, comb-like structures on the front legs of male flies (Figure 2). The obvious increase in sex combs served as a visual indicator of underlying genetic changes and the polycomb-related proteins became known as Polycomb Group (PcG) proteins. We now know PcG proteins act in multimeric complexes to remodel chromatin and epigenetically silence gene expression. In flies, PcG proteins are best known for maintaining silent expression states of Hox genes, which specify segment identity during early embryonic development. The PcG proteins are arbitrarily distinguished from the trithorax group (trxG) proteins, as the latter can maintain active expression of Hox genes. In fact, both groups of proteins alter the access of DNA to transcriptional regulators, increasing the expression of some genes and decreasing that of others.

Figure 2. The sex comb on the foreleg of male fruit flies. A.) *In situ*. B.) Detail.

The specific actions of PcG and trxG proteins are diverse. Certain proteins of the complex act as adapters, binding DNA and proteins and then recruiting other complex components. By analogy, these proteins connect the active part of the complex to the site of action, much as a tool's handle (with the

Figure 3. Important multicomponent 'complexes'. A.) A staple gun. B.) The PcG complex, PRC2. Each has adapter components for interacting with other things, a functional unit that does the work, and a part that helps, but does not drive, the function. Each 'complex' adds specific units in a directed and controlled manner. C.) The PRC2 complex interacting with the nucleosome, ready to apply a methyl group to H3K27.

hand) moves the tool to where it will work (Figure 3). Functional proteins include methyltransferases, deacetylases, and RING-domain proteins which facilitate ubiquitinylation, as well as enzymes that mediate ATP-dependent remodeling of nucleosome structure, physically moving DNA to allow transcription. In addition, complexes contain structural proteins that are necessary for the enzymes to function. Like a trigger on a gun or the tip on a pipettor, they don't actually do the work, but they play important roles in getting the work done.

Enhancing Zeste: EZH2

The different players on each of the PcG and trxG teams are not interchangeable. Instead, they interact loyally as supporting members of identifiable complexes. For example, the catalytic subunit of Polycomb Repressive Complex 2 (PRC2) is EZH2 (human) or E(z) in flies.^{7,8} Suppressor of zeste-12 homolog (SUZ12) and histone-binding retinoblastoma binding protein 4 (RBBP4) form the minimal nucleosome binding module of PRC2 (Figure 3). That is, together they identify the appropriate binding site on nucleosomes and act as an adaptor by holding EZH2 in place. EED (embryonic ectoderm development) is required for the methyltransferase activity of EZH2, which targets primarily lysine 27 on histone 3 (H3K27). SUZ12, RBBP4, and EED are mammalian homologs of the *Drosophila* proteins Su(z)12, Extra sex combs-like (Esl), and chromatin assembly factor 1 (Caf1, also known as nucleosome-remodeling factor 55 (NURF-55)).

Several other proteins can interact around this core complex. For example, the fly Pcl (polycomblike)/ mammalian PHF1 (PHD finger 1) appears to be a facultative partner in PRC2, serving to increase KMT activity and/or facilitate binding of PRC2 to targets. The fly proteins Rpd3 (mammalian homolog: histone deacetylase 1, HDAC1) and Sir2 (mammalian homolog: sirtuin 1, SIRT1), can associate with PRC2 and remove acetyl groups from histones and other proteins. PRC2 commonly associates with a completely different team of polycomb repressive proteins, PRC1, whose active member

Sex combs extra (Sce; RNF2) ubiquitinylates histone 2. Finally, PRC2 may also serve as a recruiting platform for DNA methyltransferases. Thus, the polycomb repressor complex combines protein methylation, protein deacetylation, ubiquitinylation, and DNA methylation to suppress gene expression epigenetically.

Aberrant EZH2 function has been documented in several types of human cancer, most notably prostate and breast cancer.^{9,10} Most commonly, EZH2 is found to be overexpressed in cancerous tissues; overexpression may be induced by IL-6, can result from overexpression of the E2F transcription factors, or may result from gene amplification.¹¹⁻¹³ This presents the apparent paradox of increased activity of EZH2, which represses gene expression, somehow causing cancer. One explanation hinges on the "cancer stem cell hypothesis", which suggests that undifferentiated or dedifferentiated precursor cells may play key roles in oncogenesis.¹⁴ EZH2-containing PRC2 is commonly found to be associated with the transcription factors Oct4, Sox2, and Nanog, which play critical roles in programming embryonic stem cell gene expression to maintain pluripotency. In this context, EZH2 is viewed as a co-repressor, inhibiting the differentiation program of stem cells and contributing to embryonic stem cell self-renewal. Complementing this suppressive effect, EZH2 activates pro-growth signaling cascades. In this way, increased expression of EZH2 pushes cell differentiation further toward a pluripotent, and oncogenic, phenotype.

Recent Developments for EZH2

A quick look at PhosphoSitePlus indicates that EZH2 can be phosphorylated on multiple sites, as documented by phosphoproteomics studies. Unfortunately, little is known about the importance of these alterations. More traditional studies report that phosphorylation of EZH2 on threonine 345 by cyclin-dependent kinases CDK1 and CDK2 (in a cell cycle-regulated fashion) increases binding of noncoding RNAs (ncRNA) to EZH2 and PRC2.^{15,16} This may help PRC2 bind complementary chromatin domains, contributing to the specificity of PRC2 signaling. Curiously, CDK1 can also phosphorylate Thr 487, disrupting EZH2 binding to PRC2, inhibiting methyltransferase activity, and promoting cell differentiation.¹⁷

The type or amount of methylation by PRC2 may be determined by mutations on EZH2. Multiple somatic mutations of tyrosine 641 occur in B-cell lymphomas.¹⁸ *In vitro* analysis suggests that WT EZH2 is most efficient at adding one or two methyl groups to H3K27, while the Y641 mutant efficiently di- and trimethylates the site.^{19,20} The somatic mutation always occurs in one allele, producing heterozygous pairing of WT and Y641 mutants. The presence of both forms of EZH2 augments the conversion of H3K27 to the trimethylated, most repressive form. Thus mutation is a second way, after increased expression, of increasing trimethylation of H3K27, suppression of cell differentiation, and promotion of oncogenesis.

I2PP2A/SET Polyclonal Antibody 13782

Inhibitor of Granzyme A-activated DNase, PHAPII, Phosphatase 2A Inhibitor, Template-Activating Factor I

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptides from human I2PP2A/SET amino acids 79-94 and 148-164 • **Host:** rabbit • **Cross Reactivity:** (+) human I2PP2A/SET • **Application(s):** WB • I2PP2A/SET is a multitasking protein, involved in apoptosis, transcription, nucleosome assembly, and histone binding. The SET gene produces two isoforms from transcript variants. Isoform 1 and 2 interact directly with each other and with ANP32A within the tripartite inhibitor of acetyltransferases complex, inhibiting EP300/CREBBP and PCAF-mediated acetylation of histones. The two isoforms differ in their amino termini but are identical through the regions used as antigens for preparing this antibody.

Olivia May, Ph.D.

Phospholipase D Signaling in Cancer

Over the past several decades evidence for the involvement of phospholipids in cancer has been mounting. As a critical regulator of cell proliferation and survival, elevated PLD activity and overexpression has been implicated in multiple human cancers including breast, renal, gastric, thyroid, and colorectal. PLD activity is increased in response to mitogenic signals and activated oncoproteins, and its enzymatic product, phosphatidic acid (PA), can act as a tumor promoting second messenger that recruits critical signaling molecules to membranes. Inhibition of PLD enzymatic activity leads to increased cancer cell apoptosis, decreased cancer cell invasion, and decreased metastasis of cancer cells. Articulated below are some of the newer discoveries regarding PLD's role in cancer and the research tools being developed to further this understanding.

PLD, the Basics

PLD catalyzes the conversion of membrane phospholipids to the lipid second messenger PA and a polar head group. (Figure 1) Two mammalian isoforms of PLD have been characterized, PLD1 and PLD2. Structural similarities between the two isoforms are highlighted by 53% shared sequence identity, including the conserved phox consensus sequence (PX), pleckstrin homology (PH), and phosphatidylinositol and (4, 5) and diphosphate (PIP₂) binding domains as well as the histidine, lysine, aspartate (HKD) catalytic sites. Despite these similarities, PLD1 and PLD2 are subject to different regulatory mechanisms with distinct patterns of expression. PLD1 has low basal activity that is highly regulated by protein kinase C (PKC) and the small GTPase proteins Arf and Rho, is localized to intracellular membranes, and participates in vesicle trafficking. PLD2 is constitutively active in many cell types and mediates a number of unique protein interactions when key tyrosine residues are phosphorylated in response to mitogens or growth factors. PLD2 was described originally as being localized to the plasma membrane, but subsequent studies have shown that PLD2 can have a cytosolic distribution. It is activated in intact cells by agonists binding to G-protein-coupled receptors and can be regulated by small GTP binding proteins, heterotrimeric GTP-binding proteins, and PKC isoforms. PLD1 can also be phosphorylated on tyrosine, but this modification has not been shown to lead to a significant change in activity. The distinct roles of the individual PLD isoforms remain to be fully delineated but are noted below when possible.

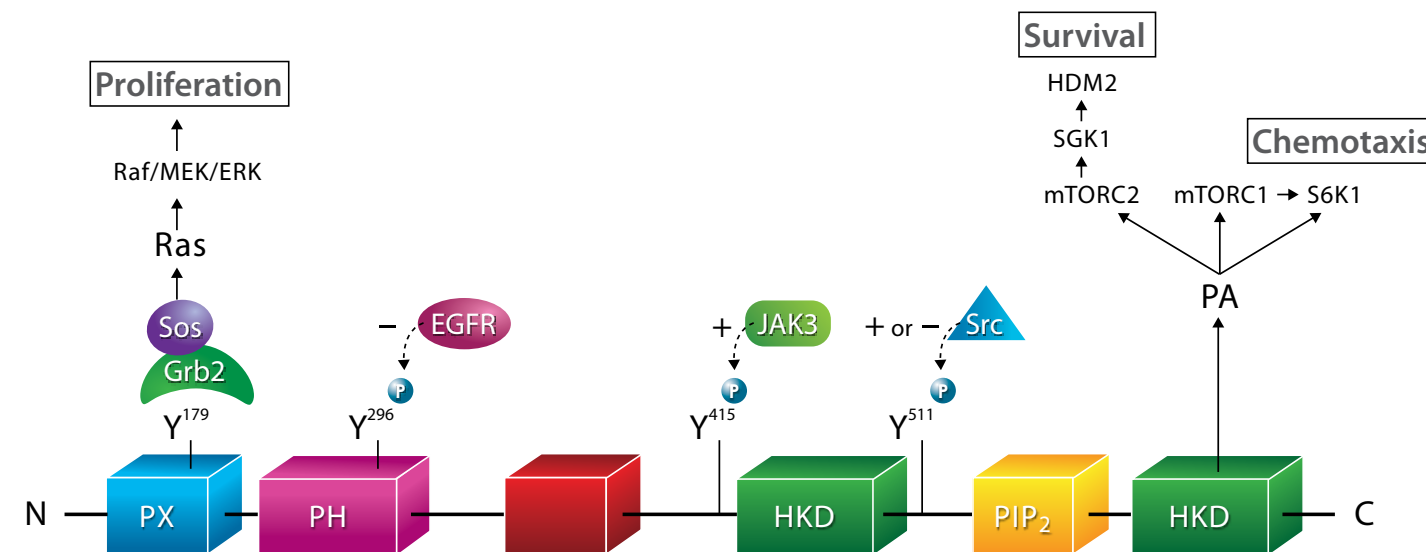

Tyrosine Phosphorylation of PLD2, Promoting Transformation

The enzymatic activity of PLD2 is complexly regulated by phosphorylation and dephosphorylation at specific activation and inhibitory sites. Recent *in vitro* studies report that at least three kinases, EGFR, JAK3, and Src are capable of phosphorylating PLD2 at tyrosine residues 296, 415, and 511, respectively.¹ (Figure 2) Upon phosphorylation, Y²⁹⁶ and Y⁴¹⁵ have inhibitory and activational functions, respectively, the extent of which is context dependent. Phosphorylation of Y⁵¹¹ can yield either inhibition or activation depending on cell type. For example, COS-7 cells, which have high levels of PLD2 activity, are prominently phosphorylated by JAK3 on the Y⁴¹⁵ activation site and moderately phosphorylated by EGFR kinase and Src on Y²⁹⁶ and Y⁵¹¹, respectively. Conversely, in MCF-7 cells, an estrogen receptor positive, breast cancer cell type characterized by low PLD2 activity and delayed cell transformation, EGFR kinase prominently phosphorylates the Y²⁹⁶ inhibitory site of PLD2. Modest input from JAK3 at the Y⁴¹⁵ activation site does not compensate for the negative modulation by EGFR kinase in MCF-7 cells, thus PLD2 activity is muted. Undoubtedly the interplay of phosphorylation on key tyrosine residues is cell-type specific as PLD2 can transform rat fibroblasts overexpressing c-Src or EGFR. Phosphatase activity at the inhibitory and activator sites of PLD2 also intricately regulates production of PA.

The phosphotyrosine motifs *p-YxN* at sites Y¹⁷⁹ and Y⁵¹¹ on PLD2 additionally serve as docking sites for growth factor receptor bound protein 2 (Grb2).² When Grb2 is bound, PLD2-generated PA can recruit Sos, an activator of the Ras oncogene, to the plasma membrane. (Figure 2) Through activation of the Ras GTP/GDP exchange, PA is connected to downstream signaling of the Raf/MEK/ERK mitogen-activated protein kinase cascade, which is critical for cell proliferation/transformation.

PA Contributes to Cell Survival Through mTOR

Many of the oncogenic effects of PA can be attributed to its downstream targets mTOR (mammalian target of rapamycin), a serine-threonine kinase that regulates cellular activities in response to environmental stress, and S6K1, the p70 ribosomal protein S6 kinase 1. Both mTOR complexes, mTORC1 and mTORC2, are dependent on PLD-derived PA for activation. (Figure 2) The raptor-associated mTORC1/S6K1 signaling

PLD2

Figure 2. A protein map of PLD2 indicating the tyrosine phosphorylation targets discussed in this article. Recruitment of Grb2 and Sos connects PLD to the Raf/MEK/ERK signaling cascade. Phosphorylation by the kinases EGFR, JAK3, and Src has distinct inhibitory and/or activational activities on specific tyrosine residues. The HKD catalytic domain of PLD enables production of PA, which becomes an important signaling component of the mTORC1, S6K1, and mTORC2 pathways.

cascade phosphorylates downstream targets involved in cell survival, cell migration, growth, and proliferation and thus, is most often associated with oncogenesis. As a negative feedback mechanism in the upstream direction, mTORC1 and S6K1 are capable of down-regulating levels of PLD2 gene expression. Whereas abnormally high levels of mTORC1 are thought to be an underlying cause in many cancers, elevated PLD activity signaling through mTORC2 and the serum- and glucocorticoid-inducible kinase 1 (SGK1) has been specifically shown to increase levels of human double minute 2 protein (HDM2), a p53 E3 ubiquitin ligase.³ (Figure 2) When activated, HDM2 counters the pro-apoptotic signaling mediated by p53, thus further contributing to cancer cell survival.

PLD's Role in Cell Migration and Metastasis

PLD activity is important for cell mobility and migration. Overexpression of PLD2 can result in reorganization of the actin cytoskeleton, which plays a significant role in cell motility, whereas PLD2 knockdown leads to cell migration arrest. PA production through PLD activates mTOR/S6K (specifically S6K), which leads to actin polymerization and chemotaxis.⁴ The association of Grb2 with PLD2 is capable of recruiting Wiskott-Aldrich syndrome protein (WASP) a protein that also potentiates actin polymerization.⁴ Additionally, PLD-generated PA has been demonstrated to recruit DOCK2, the guanine nucleotide exchange factor of Rac1, to the leading edge of polarizing cells, resulting in increased actin polymerization.⁴ Inappropriate cell motility accelerates the spread of cancer cells, and PLD activity has been implicated in tumor invasion. As one simple example, the ability of MDA-MB-231 human breast cancer cells (with high PLD activity) to migrate and invade a synthetic matrix is PLD dependent, unlike MCF-7 breast cancer cells, a low-invasive form of breast cancer with endogenously low PLD activity.⁵ Invasive cancer cells also secrete proteases to promote metastasis. PLD activity has been correlated with increased protease secretion. Increased expression of PLD activity has been shown to stimulate secretion of a host of matrix metalloproteinases (MMPs) in a number of different cancer cells.⁵

Isoform-selective Inhibitors, New Hope for Treating Cancer

Original studies of PLD function widely relied on short-chain primary alcohols such as ethanol or *n*-butanol to competitively block phosphatidic acid production. These alcohols serve as competitive nucleophiles to water, resulting in a transphosphatidyl reaction that generates phosphatidylalcohol products instead of PA. Whereas phosphatidylalcohols are relatively inert and stable when incorporated into biological membranes and are useful for assaying PLD activity, they are indirect inhibitors of PA production and are not viable options for therapeutic use. With a burgeoning understanding of the role of PLD in cell proliferation, transformation, chemotaxis and metastasis, the availability of small-molecule, isoform-specific PLD inhibitors promises to help further define the respective roles of PLD1 and PLD2 and to potentially serve as a new approach for the treatment of cancer. For your research purposes, Cayman offers halopemide (Item No. 13205) and FIPI (Item No. 13563), both potent yet non-specific PLD inhibitors as well as CAY10593 (Item No. 13206) and CAY10594 (Item No. 13207), novel PLD1- and PLD2-specific inhibitors, respectively, designed and characterized by Dr. Alex Brown's group at Vanderbilt University.⁵⁻⁷

Figure 1. Phospholipase D hydrolyzes membrane phospholipids. For example, phosphatidylcholine is cleaved into phosphatidic acid and choline. Phosphatidic acid acts as a second messenger involved in intracellular protein trafficking, cytoskeleton organization, cell proliferation, and cancer cell transformation.

JC-1 Mitochondrial Membrane Potential Assay Kit 10009172

Stability: ≥6 months at -20°C

Summary: Mitochondrial membrane potential, $\Delta\psi_m$, is an important parameter of mitochondrial function that is used as an indicator of cell health. JC-1 is a lipophilic, cationic dye that can selectively enter into mitochondria and reversibly change color from green to red as the membrane potential increases. In healthy cells with high mitochondrial $\Delta\psi_m$, JC-1 spontaneously forms complexes known as J-aggregates with intense red fluorescence. On the other hand, in apoptotic or unhealthy cells with low $\Delta\psi_m$, JC-1 remains in the monomeric form, which shows only green fluorescence. Cayman's JC-1 Mitochondrial Membrane Potential Assay provides all the necessary reagents, as well as complete instructions, for analysis of mitochondrial integrity in whole cells.

100 tests

Effect of staurosporine on mitochondrial potential in Jurkat cells. Left Panel: untreated cells show most of the cells had strong J-aggregation (red). Right Panel: staurosporine-treated cells show a majority of cells stained green due to low $\Delta\psi_m$.

JMJD2A (human recombinant) 10336

JHDM3A, Jumonji Domain Containing 2A, KDM4A, Lysine-Specific Demethylase 4A
Purity: ≥85%

Supplied in: 50 mM Hepes, pH 7.4, containing 150 mM sodium chloride and 20% glycerol **Stability:** ≥6 months at -80°C

Summary: recombinant N-terminal His-tag protein expressed in *E. coli* • M_r : 43.0 kDa • JMJD2A catalyzes the demethylation of tri- and di-methylated forms of histone H3 at lysine residues 9 and 36. Its transcriptional function appears to depend on protein associations, as it is implicated in both transcriptional silencing and upregulation of the androgen receptor-dependent genes. The jumonji C domain-containing histone demethylases have been implicated in cancer cell growth and may be drug discovery targets for therapeutic intervention.

JMJD2A Inhibitor Screening Assay Kit 700360

Jumonji Domain Containing 2A, KDM4A, Lysine-Specific Demethylase 4A

Stability: ≥6 months at -80°C

Summary: JMJD2A is a Jumonji C (JmjC) histone demethylase that catalyzes the demethylation of di- and trimethylated lysine 9 and lysine 36 of histone H3. Cayman's JMJD2A Inhibitor Screening Assay is based on the detection of formaldehyde produced during the demethylation of the trimethylated peptide substrate, histone H3 trimethyl lys9. Cyclization of formaldehyde and acetoacetanilide in the presence of ammonia gives a fluorescent product for quantitation.

96 wells

JMJD2A Polyclonal Antibody 10382

Jumonji Domain Containing 2A, KDM4A, Lysine-Specific Demethylase 4A

Supplied as: IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: human recombinant JMJD2A amino acids 1-350 • Host: rabbit • Cross Reactivity: (+) human JMJD2A • Application(s): WB • JMJD2A is a lysine specific demethylase with emerging roles in histone modification or epigenetic remodeling. This JMJD2A polyclonal antibody was raised against an N-terminal recombinant fragment of JMJD2A. This fragment (amino acids 1-350) includes the JmjN and JmjC domains but not the two LAP/PHD zinc finger or Tudor domains of the 1,064 amino acid protein.

500 μ l

JMJD2D (human recombinant) 10335

Jumonji Domain Containing 2D, KDM4D, Lysine-Specific Demethylase 4D

Purity: ≥95%

Supplied as: A solution in 50 mM Hepes, pH 7.4, containing 150 mM sodium chloride and 20% glycerol

Summary: Source: Human recombinant N-terminal His-tagged protein, expressed in *E. coli* • M_r : 42.7 kDa

JMJD2D Polyclonal Antibody 10383

Jumonji Domain Containing 2D, KDM4D, Lysine-Specific Demethylase 4D

Supplied as: Antigen-affinity purified rabbit IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: human recombinant JMJD2D amino acids 1-354 • Host: rabbit • Cross Reactivity: (+) human and murine JMJD2D • Application(s): FC, ICC, IP, and WB • JMJD2D is a lysine specific demethylase with emerging roles in histone modification or epigenetic remodeling. This JMJD2D polyclonal antibody was raised against an N-terminal recombinant fragment of JMJD2D.

500 μ l

JMJD6 Peptide Affinity-Purified Polyclonal Antibody 13787

Jumonji Domain Containing 6, PTDSR

Supplied as: Antigen affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptide corresponding to human JMJD6 amino acids 127-144 • Host: rabbit • Cross Reactivity: (+) chimpanzee, ovine, canine, equine, human, murine, and opossum JMJD6 • Application(s): WB • JMJD6 is a 403 amino acid nuclear protein that acts as a bifunctional arginine demethylase and lysyl-hydroxylase. JMJD6 demethylates histone H3 at 'Arg-2' and histone H4 at 'Arg-3' and is known to function in the differentiation of multiple organs during embryogenesis, and regulate hematopoietic differentiation and macrophage cytokine responses.

15-Lipoxygenase-2 Polyclonal Antibody 10004454

Arachidonate 15-LO Type II, 15-LOX-2

Supplied as: Peptide affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: human 15-LO-2 amino acids 161-179 • Host: rabbit • Cross Reactivity: (+) human 15-LO-2; (-) rabbit reticulocyte 15-LO-1 and porcine leukocyte 12-LO-1 • Application(s): WB • 15-LO-2 oxygenates C15 of arachidonic acid to produce 15(S)-HETE. Expression of 15-LO-2 appears to be restricted to prostate, lung, skin, and cornea and may play a role in the normal development of these tissues.

500 μ l

LSD1 (human recombinant) 10245

AOF2, BHC110, KDM1, Lysine-specific demethylase-1, NPAO, p110b

Supplied as: A solution in sodium phosphate, pH 7.2, containing 100 mM sodium chloride and 20% glycerol **Stability:** ≥6 months at -80°C

Summary: Source: human recombinant N-terminal His-tagged enzyme expressed in *E. coli*; BC048134 • **M_r:** 94 kDa • LSD1 is a component of several histone deacetylase co-repressor complexes including HDAC1 and 2, CtBP, and the neuronal CoREST complexes. LSD1, with the help of its cofactor CoREST, specifically demethylates mono- and dimethylated histone H3 lysine 4, resulting in transcriptional repression.

LSD1 Inhibitor Screening Assay Kit 700120

Lysine-Specific Demethylase 1

Stability: ≥6 months at -80°C

Summary: LSD1 is a histone demethylase whose actions on specific lysine residues alter transcription of chromosomal DNA. It also inhibits the tumor suppressor activity of p53 by demethylating a specific lysine residue. Cayman's LSD1 Inhibitor Screening Assay is based on a coupled enzymatic reaction in which LSD1 first produces H₂O₂ during the demethylation of lysine 4 of a histone 3 peptide. In the presence of horseradish peroxidase, H₂O₂ reacts with ADHP to produce the highly fluorescent compound resorufin. Sufficient human recombinant LSD1 is provided for 100 tests.

Lysosome/Cytotoxicity Dual Staining Kit 600310

Stability: ≥1 year at -20°C

Summary: Cayman's Lysosome/Cytotoxicity Dual Staining Kit is a tool for studying lysosome function at the cellular level. The kit employs 4-nitro-7-(1-piperazinyl)-2,1,3-benzoxadiazole (NBD-PZ), which is membrane permeable and reacts with carboxylic acids in the acidic luminal environment of lysosomes, as a probe for the detection of lysosomes in cultured cells. Propidium iodide is used as a marker of cell death. Chloroquine, a known inhibitor of lysosome function, is included as a positive control. The kit provides sufficient reagents to effectively treat/stain up to 10 plates worth of cells irrespective of the number of wells/plate.

1 ea

Chloroquine increases lysosome accumulation but not cell death in HepG2 cells as measured by fluorescent microscopy. *Panel A:* HepG2 cells treated with vehicle. There was a basal level of lysosome staining, indicated by faint green staining of NBD-PZ. Few dead cells were detected (red nuclei staining by propidium iodide). *Panel B:* HepG2 cells treated with 12.5 µM chloroquine. Note the increase in NBD-PZ fluorescence intensity but not the number of propidium iodide positive dead cells compared to the cells treated with vehicle.

S-[2-(hexadecyloxy)-1-(hydroxymethyl)ethyl]ester, ethanethioic acid

Malachite Green Phosphate Assay Kit 10009325

Stability: ≥6 months at 4°C

Summary: Cayman's Malachite Green Phosphate Assay provides a fast, reproducible, colorimetric method for measuring inorganic free phosphate in aqueous solutions. Applications for this assay include quantification of phosphorylation and phosphate release from protein phosphatase substrates. The assay is formatted to a 96-well plate, but could easily be modified for use in 384-well or cuvette-based assays.

96 wells

Mammalian STE-20-Like Kinase 1 Polyclonal Antibody 13776

KRS2, MST-1, STK4

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptide from human MST-1 amino acids 372-390 • Host: rabbit • Cross Reactivity: (+) human MST-1 • Application(s): WB • MST-1 is a serine/threonine kinase that, upon cleavage, has been implicated in the promotion of chromatin condensation. The C-terminus of MST-1 contains two functional nuclear export signals, which are released upon caspase-mediated cleavage. The N-terminus portion of the protein then translocates to the nucleus and promotes chromatin condensation at sufficiently high levels. Full-length MST-1 is localized to the cytoplasm.

Metastasis Associated 1 Family Member 2 Polyclonal Antibody 13778

MTA2, MTA-L1 Protein, p53 Target Protein in Deacetylase Complex, PID

Supplied as: Antigen affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptide from a portion of human MTA2 amino acids 650-700 • Host: rabbit • Cross Reactivity: (+) chimpanzee, human, and Rhesus monkey MTA2 • Application(s): IHC and WB • MTA2 is a nuclear protein that interacts with HDAC1 and HDAC2 and has a functional role in chromatin remodeling and deacetylase activity. It interacts with p53 and represses p53-dependent transcriptional activation, thereby regulating p53-mediated cell growth arrest and apoptosis.

1 ea

2-Methoxyestradiol EIA Kit 582261

2-Hydroxyestradiol 2-methyl ester, 2-ME2

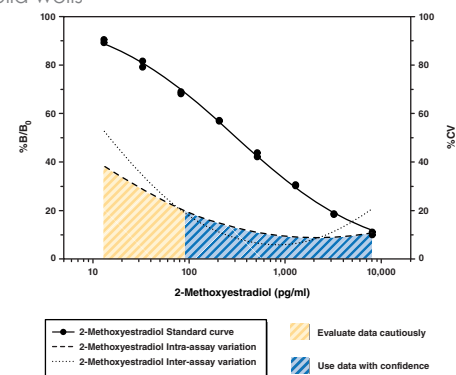

Stability: ≥1 year at -20°C

Sensitivity: 50% B/B₀: 350 pg/ml • 80% B/B₀: 40 pg/ml

Summary: 2-ME2 is a natural metabolite of estradiol with potent antitumor and antiangiogenic properties. Cayman's 2-Methoxyestradiol EIA is a competitive assay that can be used for quantification of 2-ME2 in plasma, urine, and other sample matrices.

96 strip/solid wells

480 strip/solid wells

Methylated Lysine Polyclonal Antibody 13727

Supplied as: Affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: methylated KLH • Host: rabbit • Cross Reactivity: (+) methylated lysine residues • Application(s): ELISA, IHC, IP and WB • Lysine can be methylated once, twice, or three times by lysine methyltransferases. The transfer of methyl groups from SAM to histones is catalyzed by histone methyltransferases.

400 µl

Methylated Lysine Polyclonal Antibody-biotin 13728

Supplied as: Affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: methylated KLH • Host: rabbit • Cross Reactivity: (+) methylated lysine residues • Application(s): ELISA, IP, and WB • Lysine can be methylated once, twice, or three times by lysine methyltransferases. The transfer of methyl groups from SAM to histones is catalyzed by histone methyltransferases.

400 µl

Methylated Lysine Polyclonal Antibody HRP Conjugate 13729

Supplied as: Affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: methylated KLH • Host: rabbit • Cross Reactivity: (+) multi-species • Application(s): ELISA and WB • Lysine can be methylated once, twice, or three times by lysine methyltransferases. The transfer of methyl groups from SAM to histones is catalyzed by histone methyltransferases.

Methyl-CpG-Binding Domain 1 Monoclonal Antibody (Clone 100B272.1) 13771

MBD1

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptide corresponding to human MBD1 amino acids 391-405 • Host: mouse, clone 100B272.1 • Isotype: IgG₁ • Cross Reactivity: (+) human MBD1 • Application(s): WB • DNA methylation, or the addition of methyl groups to cytosine bases in the dinucleotide CpG, is imperative to proper development and regulates gene expression. The methylation pattern involves the enzymatic processes of methylation and demethylation associated with a MBD. MeCP2 and MBD1 (PCM1) repress transcription by binding specifically to methylated DNA.

1 ea

Methyl-CpG-Binding Domain 1 Polyclonal Antibody 13772

MBD1

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: mixture of synthetic peptides corresponding to amino acids 98-113 and 391-405 of human MBD1 • Host: rabbit • Cross Reactivity: (+) human MBD1 • Application(s): WB • DNA methylation plays an essential role in mammalian development. MBD1 contains an MBD that allows it to bind specifically to methylated DNA and to repress transcription from methylated gene promoters.

1 ea

Methyl-CpG-Binding Domain 2-Binding Zinc Finger Polyclonal Antibody 13777

HINFP, Histone H4 Transcription Factor, MBD2-Binding Zinc Finger, MIZF

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: a mixture of synthetic peptides corresponding to amino acids 180-194, 331-346, and 371-388 of human MIZF • Host: rabbit • Cross Reactivity: (+) human MIZF • Application(s): WB • MIZF protein represses transcription by associating with MBD2 in a histone deacetylase complex.

1 ea

Methyl-CpG-Binding Protein 2 Polyclonal Antibody 13775

MeCP2

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: a mixture of synthetic peptides corresponding to amino acids 11-25 and 181-195 of human MeCP2 • Host: rabbit • Cross Reactivity: (+) human MeCP2 • Application(s): WB • MeCP2 may function as a mediator of the biological consequences of the methylation signal. It is also reported that this protein functions as a demethylase to activate transcription, as DNA methylation causes gene silencing.

1 ea

Methyl-CpG-Binding Domain 2/3 Monoclonal Antibody (Clone 106B691) 13773

MBD2, MBD3

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptide corresponding to human MBD3 amino acids 215-230 • Host: mouse, clone 106B691 • Isotype: IgG_{1κ} • Cross Reactivity: (+) human MBD2/3; also predicted to detect murine and rat MBD2/3 • Application(s): WB • MBD2 and MBD3 are members of a family of nuclear proteins related by the presence in each of a methyl binding domain. MBD2 is capable of binding specifically to methylated DNA, whereas MBD3 cannot.

1 ea

Methyl-CpG-Binding Domain 4 Polyclonal Antibody 13774

MBD4

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: a mixture of synthetic peptides corresponding to amino acids 268-282 and 337-352 of human MBD4 • Host: rabbit • Cross Reactivity: (+) human MBD4 • Application(s): ICC, IHC, and WB • MBD4 binds specifically to methylated DNA. It has homology to bacterial base excision repair DNA N-glycosylases/lyases.

1 ea

Methyltransferase Colorimetric Assay Kit 700140

MT

Stability: ≥6 months at -80°C

Summary: Cayman's MT Colorimetric Assay is a continuous enzyme-coupled assay that can continuously monitor SAM-dependent MT activities. The removal of the methyl group from SAM generates AdoHcy, which is rapidly converted to urate and H₂O₂ by an enzyme mixture provided in the kit. H₂O₂ is measured with the colorimetric reagent 3,5-dichloro-2-hydroxybenzenesulfonic acid. The assay can be used with any SAM-dependent MT.

96 wells

Methyltransferase Fluorometric Assay Kit 700150

MT

Stability: ≥6 months at -80°C

Summary: Cayman's MT Fluorometric Assay is a continuous enzyme-coupled assay that can continuously monitor SAM-dependent MTs. The removal of the methyl group from SAM generates AdoHcy, which is rapidly converted to urate and H₂O₂ by an enzyme mixture provided in the kit. The reaction between H₂O₂ and ADHP produces the highly fluorescent compound resorufin. The assay can be used with any purified SAM-dependent MT.

Multi-Parameter Apoptosis Assay Kit 600330

Stability: ≥1 year at -20°C**Summary:** Cellular events in apoptosis include loss of cell membrane asymmetry, cell shrinkage, membrane blebbing, nuclear fragmentation, and chromatin condensation. Cayman's Multi-Parameter Apoptosis Assay includes four different reagents for monitoring several events in apoptosis. It employs FITC-conjugated Annexin V as a probe for phosphatidylserine on the outer membrane of apoptotic cells, TMRE as a probe for mitochondrial membrane potential, 7-AAD as an indicator of membrane permeability/cell viability, and Hoechst Dye to demonstrate nuclear morphology. The kit allows phenotypic characterization of different cell death parameters at a single-cell level. The assay can be adapted to high content screening with appropriate equipment. The reagents provided in the kit are sufficient to run 100 samples when using flow cytometry or 500 samples when using a 96-well plate format.

5 x 96 wells

**Staurosporine induces apoptosis in Jurkat cells, as measured by nuclear morphology, a decrease in mitochondrial membrane potential, and an increase of Annexin V FITC positive cells.** Jurkat cells were plated at a density of 5 x 10⁴ cells/well in a 6-well plate. The next day, cells were treated with vehicle (control; A-C) or 2.5 μg/ml staurosporine (treatment; D-F) for five hours. Hoechst staining shows that most control cells have round and intact nuclei (Panel A) whereas staurosporine-treated cells mostly have condensed and fragmented nuclei (Panel D). TMRE staining reveals that most control cells have undisturbed mitochondrial membrane potential (Panel B) whereas staurosporine-treated cells mostly have diminished membrane potential and were not stained (Panel E). Most control cells are Annexin V negative (Panel C) whereas cells treated with staurosporine are mostly Annexin V positive (Panel F), indicating cells are undergoing apoptosis.

MutL Protein Homolog 1 Monoclonal Antibody (Clone 164C819) 13779

HNPCC, MLH1

Supplied as: Protein G-purified IgG **Stability:** ≥6 months at 4°C**Summary:** Antigen: synthetic peptide from human MLH1 amino acids 387-403 • Host: mouse, clone 164C819 • Isotype: IgG_{1κ} • Cross Reactivity: (+) human MLH1 • Application(s): WB • Human MutL Homologue (hMLH1) is homologous to the bacterial DNA mismatch repair mutL gene. Mutations in the hMLH1 gene are associated with hereditary non-polyposis colon cancer and various other cancers.

Infections in Cancer

Genetics, genomes, and even epigenetics are hot topics at cancer conferences this year. Popular in recent years, but still in the list of major symposia and mini-conferences, are molecular pathways, stem cells, and the microenvironment of the tumor. It might be easy to forget the central role that infectious agents play in causing cancer, given their disappearance from center stage at major conferences. Is there less interest in pathogens as oncogenes? A quick look at PubMed reveals that, in 2009, there were almost 200 epigenetics/cancer publications and some 2,750 stem cell/cancer papers. The same year, there were over 4,500 papers on viruses/cancer! Moreover, interest in viruses is increasing. A more thorough look through PubMed shows a nice steady rise over time in virus/cancer reports (Figure 1). Not only has the publication rate continued to climb over a 5 decade period, but it's even more impressive that it's still rising after reaching 4,000 a decade back. Moreover, it is now clear that some bacteria can cause cancer. Certainly, the role of infections in cancer deserves a closer look.

Figure 1. Annual publication rate of papers on virus/viruses AND cancer, as retrieved by PubMed

Viruses: From One Extreme to Another

At the turn of one century, 1900, there were many theories regarding the causes of malignancies. These included: 1) a transformation of cells of a tissue into cells of a different kind, 2) trauma accompanied by long-continued irritation, 3) change in control, by ovaries or testicles, of proliferation, 4) yeasts and lower fungi, and 5) parasites.¹⁻³ In this pre-gene era, transformation of cells was dismissed as an outdated concept.¹ While trauma and chronic inflammation were acknowledged as “powerful factors, and even adjuvants, in this disease”, they seemed to lack the power to generate “true cancer cells”.¹ The focus on reproductive organs foreshadowed the concept of hormones, introduced in 1902. The “inoculation into lower animals in various ways of portions of cancer growths of man”, by producing tumors, demonstrated that transformation, trauma, or ovaries were not needed to produce cancerous growth. Clearly, something was in the tumor. Several scientists reported they were able to visualize microscopic “cancer bodies” of various shapes and sizes. However, infecting animals with various bacteria, fungi, or parasites could not produce true tumors.

Viruses were first identified in the 1890's as causative agents in various animal and plant diseases. The simplest way to screen for viruses involved filtering: if a cell-free filtrate from a tissue homogenate could cause a disease, then a virus was implicated. Homogenates from tumors were tested in many different ways, including filtration, and all of the evidence suggested that cellular material that could be propagated on certain broths under specific conditions was necessary to propagate a tumor from one

Table 1. Retroviral Oncogenes

animal to another. In 1911, Francis Peyton Rous demonstrated that a cell-free filtrate from a chicken sarcoma could be transferred to another bird to induce a tumor. These results were strongly questioned at the time, in part because many others had tried the same thing with other tumors and failed. In spite of the questions, Rous lived to receive, 55 years later, a Nobel Prize for his discovery that a virus can cause a tumor. This extended period between discovery and acknowledgment underscores the doubt, supported by abundant negative experimentation over many years, that viruses can be oncogenic.

A century later, in the new millennium, the picture is clearer: while viruses can cause cancer, few can do it by themselves. Put another way, most viruses do a nice job of infecting their hosts, but only a few of these infections

go on to drive cancer. Something in those unlucky few hosts is needed in addition to the viral infection. For example, human papillomavirus (HPV) is a double-stranded DNA virus of the family Papovaviridae that includes over 100 ‘types’, based on DNA homology. Several types infect the epithelium, particularly in the anogenital region. Many types of HPV cause no symptoms, while other types induce benign papillomatous lesions of skin and mucous membranes (anogenital warts, common warts, plantar warts, laryngeal papillomas). Only a few types of HPV, including types 16 and 18, produce papillomas that may, in rare cases, progress to cancers of the anogenital region. Nearly all cases of cervical cancer are due to HPV infection, although most infections with these types of HPV do not progress to cancer. Cofactors are required for cancer development.

More about Rous' Virus

Why is the Rous sarcoma virus (RSV) oncogenic? RSV is a retrovirus, which means that it replicates by making a DNA copy of its RNA genome by reverse transcription. Some retroviruses are able to infect cells and replicate without causing cell transformation, whereas other retroviruses are highly carcinogenic. What do oncogenic retroviruses have that others do not? In the case of RSV, it's an oncogene that was named *src*, as it causes sarcomas. The RSV oncogene was renamed *v-src*, denoting its viral origin, since mammals were found to have a similar gene, *c-src* (cellular-*src*). The protein product of *v-src* is pp60^{vsrc}, a tyrosine kinase involved in signaling pathways that regulate cell movement, proliferation, and invasiveness. Oncogenes from other retroviruses encode many types of proteins that have important roles in pathways related to cell proliferation (Table 1).

Interestingly, the genome of RSV is essentially identical to that of the non-oncogenic avian leukosis virus, ALV, except that RSV contains *v-src*. It is now thought that retroviruses become oncogenic by incorporating a host cell's gene (the ‘proto-oncogene’) into the viral genome by a virus-host recombination event. In the virus, the host gene is regulated by viral promoter and enhancer elements. For this reason, oncogenes are expressed at high levels and may be transcribed in inappropriate cell types. Furthermore, the oncogene may encode a protein that differs structurally from the proto-oncogene product. For example, the viral protein may be truncated at either end, or have a portion of a different viral protein fused to it. Such deletions or insertions may result in the loss of regulatory domains that control protein activity. For example, the viral version of Raf is a fusion protein, with a second viral protein, Gag, fused where the host regulatory domain would normally be found. As a result, viral Raf is constitutively active, driving activation of kinases involved in proliferation, apoptosis and migration.

An *H. pylori* Story

Speaking of Nobel caliber work, two Australians, Robin Warren and Barry Marshall were awarded the Nobel Prize in Physiology or Medicine in 2005 for discovering the bacterium *Helicobacter pylori* and outlining its role in gastritis and peptic ulcer disease. Early in the 1980's, stress and lifestyle were considered the major causes of peptic ulcer disease. The dominant modes of treatment centered on reducing acid production using histamine H₂-receptor antagonists and, if necessary, surgery.⁴ Marshall and Warren published a report in 1984 on ‘unidentified curved bacilli’ in the stomach of patients with ulceration,⁵ and, within a decade, eradication of this new bacterium, *H. pylori*, became the focus of treatment around the world.

H. pylori is a spiral-shaped Gram-negative bacterium that colonizes the lower part of the stomach, at the antrum near the pylorus (Figure 3). The presence of *H. pylori* is always associated with inflammation of the underlying gastric mucosa with an infiltration of inflammatory cells. Chronic inflammation of the distal part of the stomach leads to increased acid production in the

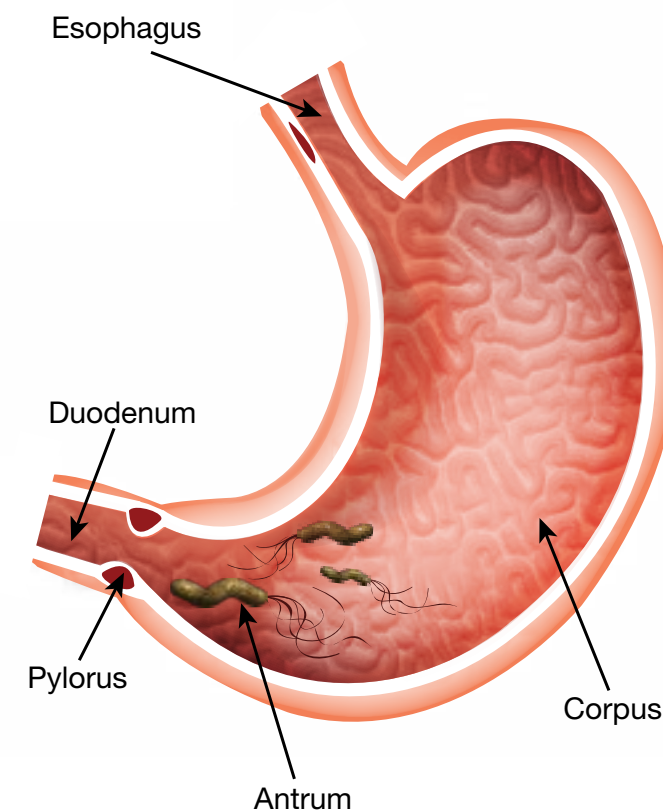

Figure 2. *H. pylori* typically reside in the antrum of the stomach, whereas the greatest acid secretion, ulceration, and tumor formation occur in the body, or corpus, of the stomach.

non-infected upper region of the stomach. *H. pylori* causes gastritis and peptic (gastric and duodenal) ulcers, but not gastroesophageal reflux disease. While over half the world's population is believed to be infected with this bacterium, infection is typically asymptomatic. On the other hand, the vast majority of peptic ulcers are caused by this pathogen.

H. pylori also causes stomach cancer. In fact, it is the first bacterium to be classified as a definite carcinogen by the World Health Organization's International Agency for Research on Cancer.⁶ While reports linking *H. pylori* and cancer emerged shortly after the bacterium's discovery, the mechanism of carcinogenesis remains elusive. Risk factors include virulence factors of the bacterium (e.g., CagA, VacA), environmental factors (diet, smoking), and host factors (gene polymorphisms).^{7,8} This brings us full circle to the ‘hot topics’ mentioned at the start of this article: genetics,⁹ epigenetics,¹⁰ molecular pathways,¹¹ and even stem cells¹² are fair game in current theories on how *H. pylori* infection leads to gastric cancer. In the end, these may just be the details that dress up the ‘trauma accompanied by long-continued irritation’ model put forth over 100 years ago.

Inhibition of network formation by JNJ-10198409. Panel A: CAPE cells suspended in culture medium containing 0.064 μM PMA or Panel B: 0.064 μM PMA + 0.3 μM JNJ-10198409 were seeded at a density of 6 x 10³ cells/well in a 96-well plate and grown in 37°C incubator for four days. On the fifth day, cells were stained with Calcein AM and the organization was examined under an inverted fluorescence microscope.

p38 MAPK (Phospho-Thr¹⁸⁰/Tyr¹⁸²) Polyclonal Antibody 10009177**Supplied as:** Affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: phosphopeptide corresponding to amino acid residues surrounding phospho-Thr¹⁸⁰ and phospho-Tyr¹⁸² of rat p38 MAPK • Host: rabbit • Cross Reactivity: (+) human p38 • Application(s): WB • p38 MAPK is activated by both inflammatory cytokines and by stress. It is thought to be particularly important in diseases like asthma and autoimmunity but it also plays important roles in the stress response of the nervous system. Like the other MAPKs, p38 is activated by a dual specificity kinase that phosphorylates Thr¹⁸⁰ and Tyr¹⁸².

1 ea

p38 MAPK (Phospho-Thr¹⁸⁰/Tyr¹⁸²) Cell-Based p53 Cell-Based Activation/Translocation Assay Kit 600008**Stability:** ≥6 months at -20°C

Summary: The tumor suppressor protein p53 plays a crucial role in coordinating cellular responses to genotoxic stress and holds many important clinical implications in the treatment of cancer. Cayman's p53 Cell-Based Activation/Translocation Assay provides a highly specific p53 primary monoclonal antibody together with a DyLight™ (product of Thermo Scientific) conjugated secondary antibody in a ready-to-use format. (-)-Nutlin-3, a potent inhibitor of Mdm2-p53 interaction is included as a positive control.

96 wells

(-)-Nutlin-3-induced translocation of p53 in MCF-7 cells. Panel A: MCF-7 cells were treated with vehicle or Panel B: 50 μM (-)-Nutlin-3 for four hours, then fixed and stained with p53 monoclonal antibody. Translocation of p53 from cytoplasm to nuclei upon stimulation by (-)-Nutlin-3 is evident.

p53 Monoclonal Antibody (Clone BP53-12) 10004806

Supplied as: Purified IgG_{2a} **Stability:** ≥1 year at 4°C

Summary: Epitope: binds to N-terminal amino acids 16-25 of wild-type and mutant p53 • Host: mouse, clone BP53-12 • Cross Reactivity: (+) human p53 • Application(s): FC, ICC, IHC (paraffin-embedded sections), and WB; this antibody does not work with frozen sections • Isotype: IgG_{2a} • Clone designation: BP53-12

1 ea

p53 (Phospho-Ser³⁹²) Polyclonal Antibody 10004807**Supplied as:** Affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: amino acids around phospho-Ser³⁹² • Host: rabbit • Application(s): WB • Nearly 50% of human tumors have mutated or non-functional p53. p53 amino acid residues can be modified by phosphorylation and acetylation. *In vivo* phosphorylation of p53 residues alters signal transduction events that warrant further investigation.

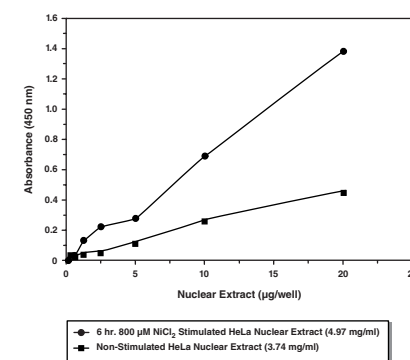

1 ea

p53 Transcription Factor Assay Kit 600020

Stability: ≥1 year at -80°C

Summary: Cayman's p53 Transcription Factor Assay is a non-radioactive, sensitive method for detecting specific transcription factor DNA binding activity in nuclear extracts. A specific dsDNA sequence containing the p53 response element is immobilized onto the wells of a 96-well plate. p53 contained in a nuclear extract binds specifically to the p53 response element and is detected by addition of a specific primary antibody directed against p53. A secondary antibody conjugated to HRP provides a sensitive colorimetric readout at 450 nm.

p66α Polyclonal Antibody 13785

*GATA Zinc Finger Domain-Containing Protein 2A, Transcriptional Repressor p66α***Supplied as:** IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptide corresponding to mouse p66α amino acids 575-585 • Host: rabbit • Cross Reactivity: (+) human, murine, and rat p66α • Application(s): WB • p66, a zinc finger-containing protein, is one of the components of the MeCP1 complex. p66 and p68, the two components of MeCP1, are different forms of the same zinc finger-containing protein and are conserved from *C. elegans* to humans. Homologs of p66 from different organisms revealed two highly conserved regions, CR1 and CR2. While CR1 is involved in the association of p66 with other MeCP1 components, CR2 plays an important role in targeting p66 and MBD3 to specific loci.

PARP (Cleaved) Monoclonal Antibody 13557

Supplied as: Protein G-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptide containing amino acids near the 214/215 cleavage site of human PARP • Isotype: IgG_{2bκ} • Host: mouse • Cross Reactivity: (+) human PARP • Application(s): FC (intracellular) and WB • PARP is a 116 kDa nuclear chromatin-associated enzyme that is cleaved during apoptosis by caspase-3 into a 24 kDa fragment containing the DNA binding domain and an 89 kDa fragment containing the catalytic and automodification domains. The 24 kDa fragment irreversibly binds to DNA and may contribute to the irreversibility of apoptosis by blocking the access of DNA repair enzymes to DNA strand breaks.

pCAF Histone Acetyltransferase (human recombinant) 10009115

*p300/(CREB binding protein) Associated Factor, HAT***Purity:** ≥95%

Supplied as: A solution in 50 mM sodium phosphate, pH 7.2, containing 100 mM sodium chloride, 1 mM EDTA, and 20% glycerol

Stability: ≥6 months at -80°C

Summary: Source: recombinant GST-tagged protein purified from *E. coli* • M_r: ~40 kDa • pCAF belongs to the GCN5/pCAF family of nuclear HATs. Cayman's pCAF preparation contains 165 amino acids from the HAT activity domain of human pCAF fused to GST at the N-terminus. Enzyme activity was determined using a fluorescent HAT assay and is comparable to that found in the literature.

PCNA Monoclonal Antibody (Clone IPO-38) 10004805

Proliferating Cell Nuclear Antigen

Supplied as: Purified IgM **Stability:** ≥1 year at 4°C

Summary: Host: mouse, clone IPO-38 • Cross Reactivity: (+) multiple species (species- and tissue-unspecific) • Application(s): FC, ICC, IHC (frozen and paraffin-embedded sections), and WB • PCNA becomes detectable in the G₁ phase of the cell cycle and reaches a maximum level of expression during mitosis. PCNA is highly conserved across species and is a critical part of the DNA polymerase holoenzyme. The level of PCNA expression depends on the proliferative potential of the cell examined.

PH Domain Leucine-rich Repeat Protein Phosphatase Polyclonal Antibody 10007191

KIAA0606 Protein, PHLPP, PLEKHE1 Protein, SCOP, Suprachiasmatic Nucleus Circadian Oscillatory Protein

Supplied as: Peptide affinity-purified IgG **Stability:** ≥1 year at 4°C

Summary: Antigen: human PHLPP amino acids 1192-1205 • Host: rabbit • Cross Reactivity: (+) human, murine, and rat PHLPP • Application(s): ICC, IHC (paraffin-embedded sections), and WB • PHLPP dephosphorylates the hydrophobic motif of Akt and thus reduces Akt activity, resulting in an increase in the number of apoptotic cells. PHLPP levels are markedly reduced in several colon cancer and glioblastoma cell lines that have elevated Akt phosphorylation.

Phagocytosis Assay Kit (IgG FITC) 500290

Stability: ≥6 months at 4°C

Summary: Cayman's Phagocytosis Assay (IgG FITC) employs latex beads coated with fluorescently-labeled rabbit-IgG as a probe for the identification of factors regulating the phagocytic process *in vitro*. The engulfed fluorescent-beads can be detected by fluorescence microscopy or flow cytometry.

1 ea

PMA induces the differentiation of THP-1 cells into phagocytic cells. THP-1 cells were treated with either vehicle (Panel A), 0.16 μM PMA (Panel B), or 1.6 μM PMA (Panel C) and at the same time loaded with Latex Beads-Rabbit IgG-FITC Complex. PMA treatment at a dose as low as 0.16 μM caused THP-1 cells to differentiate and become phagocytic, as evidenced by a significant increase in cells engulfing the Latex Beads-Rabbit IgG-FITC complex.

PI3-Kinase α Inhibitor 2 10010177

PRMT1 (human recombinant) 10350

Purity: \geq 80%**Supplied as:** A solution in 50 mM Tris-HCl, pH 8.0, containing 150 mM sodium chloride and 20% glycerol **Stability:** \geq 6 months at -80°C**Summary:** Source: human recombinant N-terminal GST-tagged protein expressed in *E. coli* • M_r: 69.2 kDa • PRMT1 is a class I arginine methyltransferase that methylates arginine residues at a number of glycine and arginine rich regions (GAR motifs) including histone H4 at arginine 3.25 μ g
50 μ g
100 μ g

PRMT4 Polyclonal Antibody 13552

CARM1

Supplied as: Protein G-purified IgG **Stability:** \geq 1 year at -20°C**Summary:** Antigen: synthetic peptide corresponding to human PRMT4 amino acid sequences 45-69 and 595-608 • Host: rabbit • Cross Reactivity: (+) human PRMT4 • Application(s): WB • PRMT4, also known as CARM1, belongs to a family of proteins that catalyzes the methylation of arginine residues.

1 ea

PRMT5 Polyclonal Antibody 13559

JBPI, Skb1HS

Supplied as: Protein G-purified IgG **Stability:** \geq 1 year at -20°C**Summary:** Antigen: synthetic peptide from human PRMT5 • Host: rabbit • Cross Reactivity: (+) human PRMT5 • Application(s): WB • PRMT5, also known as JBPI and human homolog of Skb1 of fission yeast (Skb1HS) can catalyze the formation of ω -N^G-monomethylarginine and symmetric ω -N^G,N^G-dimethylarginine in a variety of proteins. Recombinant PRMT5 can mono- and dimethylate histone 2A and myelin basic protein.

1 ea

PRMT6 Polyclonal Antibody 13558

Supplied as: Protein G-purified IgG **Stability:** \geq 1 year at -20°C**Summary:** Antigen: synthetic peptide from human PRMT6 amino acids 23-43 • Host: rabbit • Cross Reactivity: (+) human and murine PRMT6 • Application(s): WB • PRMT6 is a protein with an approximate molecular weight of 42 kDa consisting of a catalytic core sequence common to other PRMT enzymes. PRMT6 demonstrates type 1 PRMT activity, capable of forming both N^G-monomethylarginine and asymmetric N^G,N^G-dimethylarginine derivatives on recombinant glycine- and arginine-rich substrates.

1 ea

PRMT7 Polyclonal Antibody 13551

Supplied as: Protein G-purified IgG **Stability:** \geq 1 year at -20°C**Summary:** Antigen: synthetic peptide from human PRMT7 amino acid sequence 346-360 • Host: rabbit • Cross Reactivity: (+) human and murine PRMT7 • Application(s): WB • PRMT7 can catalyze the formation of ω -N^G-monomethylarginine in peptides.

15-hydroxy Prostaglandin Dehydrogenase Polyclonal Antibody 160615

15-hydroxy PGDH, PG15DH

Supplied as: Peptide affinity-purified IgG **Stability:** \geq 2 years at -20°C**Summary:** Antigen: human NAD⁺-dependent 15-hydroxy PGDH amino acids 92-105 • Host: rabbit • Cross Reactivity: (+) human, bovine, guinea pig, and baboon 15-hydroxy PGDH • Application(s): WB • NAD⁺-dependent 15-hydroxy PGDH catalyzes the oxidation of PGs to 15-keto metabolites, which have greatly reduced biological activity. Three different studies have shown an inverse correlation between 15-PGDH expression and cell proliferation in colon, breast, and thyroid cells.500 μ l• Also Available: **15-hydroxy Prostaglandin Dehydrogenase Blocking Peptide** (360615) 200 μ g
15-hydroxy Prostaglandin Dehydrogenase Western Ready Control (10009742) 1 ea

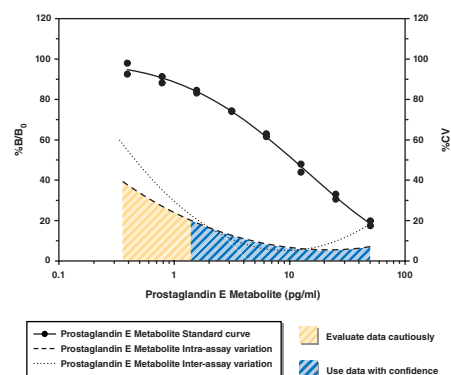

Prostaglandin E Metabolite EIA Kit

514531

PGEM

Stability: ≥1 year at -20°C**Sensitivity:** 50% B/B₀: 11 pg/ml • 80% B/B₀: 2 pg/ml

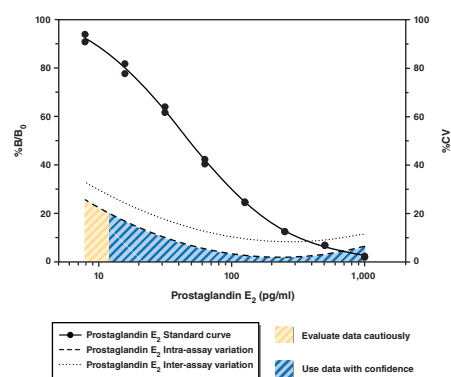

Summary: Because of the rapid metabolism of PGE₂, the determination of *in vivo* PGE₂ biosynthesis is often best accomplished by the measurement of PGE₂ metabolites. Cayman's PGEM assay converts all 13,14-dihydro-15-keto PGE₂ and 13,14-dihydro-15-keto PGA₂ into a single stable derivative, which is easily measurable by EIA. This assay is therefore the method of choice if the samples in question have undergone extensive metabolism prior to collection.

96 strip/solid wells
480 strip/solid wellsProstaglandin E₂ EIA Kit - Monoclonal

514010

Stability: ≥1 year at -20°C**Sensitivity:** 50% B/B₀: 50 pg/ml • 80% B/B₀: 15 pg/ml

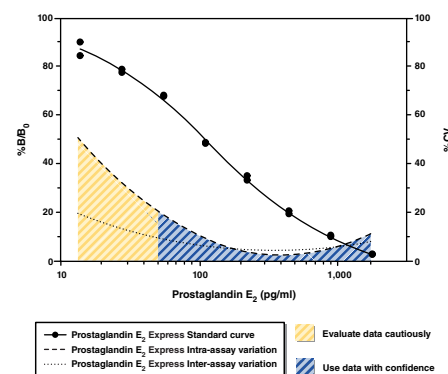

Summary: Cayman's PGE₂ EIA is a sensitive competitive assay that uses a high-affinity PGE₂ monoclonal antibody for quantification of PGE₂ in plasma, urine, and culture media samples.

96 strip/solid wells
480 strip/solid wellsProstaglandin E₂ Express EIA Kit

500141

Stability: ≥1 year at -20°C**Sensitivity:** 50% B/B₀: 125 pg/ml • 80% B/B₀: 36 pg/ml

Summary: Cayman's PGE₂ Express EIA permits the rapid measurement of PGE₂ from biological samples, requiring only one hour incubation and development times for each step.

96 strip/solid wells
480 strip/solid wells

20S Proteasome Assay Kit

10008041

Stability: ≥6 months at -80°C

Summary: The proteasome is a multicatalytic proteinase complex that is involved in the selective degradation of intracellular proteins. Proteasome inhibitors exhibit anti-inflammatory and antiproliferative effects. Cayman's 20S Proteasome Assay employs a specific 20S substrate, SUC-LLVY-AMC which, upon cleavage by the active enzyme, generates a highly fluorescent product with an emission wavelength at 480 nm.

Protein Arginine Deiminase 4 (human recombinant)

10500

PAD4

Purity: ≥95%

Supplied as: A solution in 50 mM sodium phosphate, pH 7.2, containing 100 mM sodium chloride, 1 mM EDTA, and 20% glycerol **Stability:** ≥9 months at -80°C

Summary: Source: Recombinant N-terminal His-tagged protein expressed in *E. coli* • M_r: 75.8 kDa • PAD4 is a homodimer that functions as a transcriptional coregulator to catalyze the conversion of specific arginine residues to citrulline in a calcium-dependent manner. PAD4 substrates include histones H2A, H3, and H4, whose post-translational modifications play a large role in gene regulation.

Protein Phosphatase 2A C subunit (human recombinant; L309 deletion)

10011237

PP2A Cα, PP2A L309, PP2A A³⁰⁹**Purity:** ≥90%

Supplied as: A solution in 20 mM Tris-HCl, pH 7.5, containing 100 mM sodium chloride, 1 mM EDTA, 1 mM DTT, 5 mM magnesium chloride, and 25% glycerol **Stability:** ≥6 months at -80°C

Summary: Source: human recombinant PP2A catalytic subunit expressed in insect cells with an N-terminal octahistidine-tag followed by a streptactin-tag. The C-terminal leucine 309 was deleted. • M_r: 38.6 kDa • PP2A is a divalent cation-independent protein serine/threonine phosphatase involved in regulating numerous cellular processes including the cell cycle, growth, and differentiation and is also thought to be a potential tumor suppressor.

Protein Tyrosine Phosphatase 1B (human recombinant)

10010896

PTP1B

Purity: ≥95%

Supplied as: A solution in 100 mM Tris, pH 7.2, containing 100 mM sodium chloride, 1 mM EDTA, and 25% glycerol **Stability:** ≥6 months at -80°C

Summary: Source: human recombinant protein purified from *E. coli* • M_r: 37.3 kDa • PTPs remove phosphate from tyrosine residues of cellular proteins. Reversible phosphorylation catalyzed by the coordinated actions of protein tyrosine kinases and phosphatases is of paramount importance to the regulation of the signaling events that underlie such fundamental processes as growth and proliferation, differentiation, and survival or apoptosis, as well as adhesion and motility. One of the most heavily studied PTP proteins is PTP1B.

PTEN (human recombinant)

10009746

MMAC1, Phosphatase and Tensin Homolog on Chromosome 10, Phosphatidylinositol 3-phosphatase, TEP1

Supplied as: A solution in 50 mM sodium phosphate, pH 7.2, containing 100 mM sodium chloride and 20% glycerol **Stability:** ≥6 months at -80°C

Summary: Source: human recombinant N-terminal His-tagged protein purified from Sf21 cells • M_r: 50.8 kDa • PTEN functions as a key regulatory enzyme in many signal transduction pathways by dephosphorylating proteins and lipids such as Akt and PIP₃. Mutation of PTEN results in many human cancers including melanoma and prostate carcinoma, making PTEN an important tumor suppressor.

PTEN Polyclonal Antibody

10005059

MMAC1, Phosphatase and Tensin Homolog on Chromosome 10, Phosphoinositide 3-phosphatase, TEP1

Supplied as: Peptide affinity-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: human PTEN amino acids 254-270 • Host: rabbit • Cross Reactivity: (+) human, murine, chimpanzee, canine, and rat PTEN • Application(s): IHC (paraffin-embedded sections) and WB • PTEN dephosphorylates proteins and lipids such as Akt and PIP₃ and therefore functions as a key regulatory enzyme in a central signal transduction pathway. PTEN is considered a tumor suppressor as loss-of-function mutations in PTEN often result in human cancers including melanoma and prostate carcinoma.

SET8 Methyltransferase Inhibitor Screening Assay Kit

700350

PR-Set7, SETD8, SET Domain-containing (lysine methyltransferase) 8

Stability: ≥6 months at -80°C**Summary:** SET8 is a MT that selectively mono-methylates histone H4 at lysine residue 20 (H4K20). In Cayman's SET8 MT Inhibitor Screening Assay, the transfer of the methyl group from SAM by SET8 to the acceptor peptide (H4K20) generates SAH, which is rapidly converted to urate and H₂O₂ using an enzyme mixture provided in the kit. A subsequent reaction between H₂O₂ and ADHP produces the highly fluorescent compound resorufin.

96 wells

SIRT1 Direct Fluorescent Screening Assay Kit

10010401

Stability: ≥6 months at -80°C**Summary:** The sirtuins represent a distinct class of trichostatin A-insensitive lysyl-deacetylases (class III HDACs) that catalyze a reaction coupling lysine deacetylation to the formation of nicotinamide and O-acetyl-ADP-ribose. Cayman's SIRT1 Direct Fluorescent Screening Assay provides a fluorescence-based method for screening SIRT inhibitors or activators. The procedure requires only two easy steps, both performed in the same microplate. In the first step, the substrate is incubated with human recombinant SIRT along with its cosubstrate NAD⁺. Deacetylation sensitizes the substrate such that treatment with the developer in the second step releases a fluorescent product.

96 wells

SIRT1 FRET-Based Screening Assay Kit

10010991

Stability: ≥6 months at -80°C**Summary:** Cayman's SIRT1 FRET-based Screening Assay provides a novel fluorescence-based method for screening SIRT1 inhibitors or activators. The substrate, which is coupled to a fluorophore and quencher, is first incubated with human recombinant SIRT1. Deacetylation sensitizes the substrate such that treatment with a developer separates the quencher and fluorophore resulting in bright fluorescence.

Sirtuin 2

Purity: ≥90%**Supplied as:** A solution in 50 mM sodium phosphate, pH 7.2, containing 100 mM sodium chloride and 20% glycerol **Stability:** ≥9 months at -80°C**Summary:** Source: N-terminal His-tagged SIRT2 amino acids 2-389, purified from *E. coli* • M_r: 44.2 kDa • SIRT2 is a cytoplasmic protein responsible for the deacetylation of histone H4 and α-tubulin, a modification important for controlling the cell cycle. SIRT2 co-localizes with HDAC6 and microtubules and functions as a mitotic checkpoint in preventing chromosomal instability that can lead to hyperploid cells.25 µg
50 µg
100 µg

SIRT3 Direct Fluorescent Screening Assay Kit 10011566

Stability: ≥6 months at -80°C**Summary:** Cayman's Direct Fluorescent Screening Assay Kits provide a fluorescence-based method for screening SIRT3 inhibitors or activators. The procedure requires only two easy steps, both performed in the same microplate. In the first step, the substrate is incubated with human recombinant SIRT along with its cosubstrate NAD⁺. Deacetylation sensitizes the substrate such that treatment with the developer in the second step releases a fluorescent product.

96 wells

SIRT4 (human recombinant)

10317

Sirtuin 4

Purity: ≥85%**Supplied as:** A solution in 50 mM sodium phosphate, pH 7.2, containing 100 mM sodium chloride, 2.5 mM DTT, and 20% glycerol **Stability:** ≥9 months at -80°C**Summary:** Source: Recombinant N-terminal GST-tagged SIRT4, purified from *E. coli* • M_r: 61.9 kDa • SIRT4 is a mitochondrial ADP-ribosyltransferase responsible for the transfer of ADP-ribose from NAD to specific substrates such as glutamate dehydrogenase (GDH).25 µg
50 µg
100 µg

SIRT5 (human recombinant)

10318

*Sirtuin 5***Purity:** ≥90%**Supplied as:** A solution in 50 mM sodium phosphate, pH 7.2, containing 100 mM sodium chloride and 20% glycerol **Stability:** ≥9 months at -80°C**Summary:** Source: Recombinant N-terminal GST-tagged SIRT4, purified from *E. coli* • M_r : 61.9 kDa • SIRT5 is located in the mitochondrial matrix and its functions are largely still being elucidated, however a few promising substrates have been studied. SIRT5 has been shown to deacetylate carbamoyl phosphate synthetase 1, activating the enzyme to catalyze the first step of the urea cycle.25 µg
50 µg

Sphingosine Kinase 1 (human recombinant) 10009236

Purity: ≥80% by SDS-PAGE**Supplied in:** 10 µg in 25 mM Tris-HCl, pH 8.0, containing 100 mM sodium chloride, 0.05% Tween 20, 50% glycerol, and 3 mM DTT**Stability:** ≥6 months at -80°C**Summary:** Source: human recombinant N-terminal His-tagged protein from *Sf9* cells • M_r : 46.9 kDa • SPHK 1 catalyzes the phosphorylation of sphingosine to S1P. This reaction plays an important role in determining cell proliferation *versus* cell death.

1 ea

Sphingosine Kinase 1 Inhibitor Screening Assay Kit

700430

Stability: ≥6 months at -20°C**Summary:** SPHK 1 and SPHK 2 phosphorylate *D-erythro*-sphingosine to yield S1P. S1P exhibits a broad spectrum of biological activities including cell proliferation, survival, migration, cytoskeletal organization, and morphogenesis. SPHK 1 is a potential therapeutic target for the control of cancer and inflammation. Cayman's SPHK 1 Inhibitor Screening Assay Kit provides a fluorescence-based method for screening SPHK 1 inhibitors.

96 wells

Sphingosine Kinase 1 Polyclonal Antibody 10006822

Supplied as: Peptide affinity-purified IgG **Stability:** ≥1 year at -20°C**Summary:** Antigen: human SPHK 1 amino acids 264-274 • Host: rabbit • Cross Reactivity: (+) human and murine SPHK 1, expected to react with rat SPHK 1 • Application(s): ICC and WB • SPHK 1 catalyzes the phosphorylation of sphingosine to S1P. This reaction plays an important role in determining cell proliferation *versus* cell death.

TIP60 Polyclonal Antibody

13789

KAT5, Lysine Acetyltransferase 5

Supplied as: Protein A-purified IgG **Stability:** ≥1 year at -20°C

Summary: Antigen: synthetic peptide within the region of human TIP60 amino acids 480-530 • Host: rabbit • Cross Reactivity: human (isoform CRA_b), chimpanzee, orangutan, equine, canine, murine, ovine, rat, opossum, zebrafish, and *Xenopus* TIP60 • Application(s): IHC and WB • TIP60 belongs to the MYST family of HATs. It is a catalytic subunit of the NuA4 HAT complex which is involved in transcriptional activation of select genes principally by acetylation of nucleosomal histone H4 and H2A.

1 ea

TNF-α (human) EIA Kit

589201

Stability: ≥1 year at -20°C

Limit of Detection: 3.9 pg/ml

Summary: Cayman's TNF-α assay is an immunometric sandwich EIA that permits TNF-α measurements within the range of 0-250 pg/ml, typically with a limit of detection of 3.9 pg/ml. Inter- and intra-assay CV's of less than 5% can be achieved at most concentrations. This assay allows sensitive, specific analysis of TNF-α in serum or plasma.

WST-1 Cell Proliferation Assay Kit

10008883

Stability: ≥1 year at -20°C**Summary:** Cayman's WST-1 Proliferation Assay is based on the reduction of tetrazolium salt WST-1 to soluble formazan by electron transport across the plasma membrane of dividing cells. This kit will also allow investigators to screen drug candidates involved in cell cycle regulation.96 wells
